Data for analysis has been obtained from the prowess database of Centre for Monitoring of Indian Economy (CMIE). The data starting set is CNX 500 companies which accounts for about 95.77 per cent of the free float market capitalization of the stocks listed on NSE as on 31 March 2015. Data for above companies have been selected for five financial years from 2010 to 2014 (ending on 31st March of respective year). Banks and financial companies (78 out of 500) were excluded from our sample because of their different accounting structure, which makes it difficult to calculate the financial ratios used in study and previous authors' example in this type of analysis (Yatim *et al.*, 2006; Yammeesri and Kanthi Herath, 2010; Jackling and Johl, 2009; Black *et al.*, 2010; Mustapha and Ahmad, 2011; Di Vito and Bozec, 2012; Kumar and Singh, 2013). Further, we deleted companies that did not have full data set for all variables under study for relevant five years. Hence, we were left with 391 companies with five-year data, resulting in 1955 data points. For some of the missing data, for example, data on number of board meetings, data on CEO duality for some companies for some years, we extracted data directly from the annual reports of respective companies.

5.2 Model and variables

To test the effect of board structure on firm performance we propose following models:

$$\begin{aligned}\text{Tobin's Q} = \text{f}\,(&\text{percentage of independent directors, CEO duality, board size,}\\ &\text{number of board meetings, internal busyness of directors,}\\ &\text{external busyness of directors as director in other companies,}\\ &\text{external busyness of directors as committee members in other}\\ &\text{companies, firm size, firm age, leverage, sales growth}) + e_{it}\end{aligned}$$

$$\begin{aligned}\text{ROA} = \text{f}\,(&\text{percentage of independent directors, CEO duality, board size,}\\ &\text{number of board meetings, internal busyness of directors,}\\ &\text{external busyness of directors as director in other companies,}\\ &\text{external busyness of directors as committee members in other}\\ &\text{companies, firm size, firm age, leverage, sales growth}) + e_{it}\end{aligned}$$

where i and i represent the firm and periods, respectively, and e_{it} is the error term.

Researchers have used different parameters to measure firm performance, namely, market-based and accounting-based. Tobin's Q as a performance measure is commonly used as a dependent variable (Perfect and Wiles, 1994; Agrawal and Knoeber, 1996; Loderer and Peyer, 2002; Reddy *et al.*, 2008; Kumar and Singh, 2013). Tobin's Q ratio, which is a marked-based performance measure, is calculated as the market value of common stock and preferred stock plus book value of debt divided by the book value of assets.

ROA has been used as an accounting-based performance measure by different studies, namely, Demsetz and Villalonga (2001), Fich and Shivdasani (2006) and Thomsen *et al.* (2006). ROA has been defined as the after tax net operating income divided by the total operating assets (Copeland *et al.*, 2000). Net operating income is computed as the operating earnings before income and taxes, before extra-ordinary items and prior adjustment. Prowess database of CMIE has an item called PBDITA (profit before depreciation interest and tax) prior to extra-ordinary items. It has been used as a proxy for net operating income.

Demsetz and Villalonga (2001) argue that although the numerator of Tobin's Q partly reflects the value that investors assign to a company's intangible assets, the denominator does not include the investment a company has in intangible assets, such as advertisement and research and development. These items are simply treated as expenses. To overcome this problem, some studies have used depreciated value of tangible assets. The accounting-based profit measure is criticised for being backward-looking and it estimates future events only partially in the form of depreciation and amortization. On the other hand, Tobin's Q is greatly influenced by a wide range of unstable factors, such as investors' psychology and market forecasts (Reddy *et al.*, 2010). For this reason, we have used both the performance measures in this study.

Control variables used in the study are size of firm, age of firm, financial leverage used by firm and sales growth of firm.

Size of the company in terms of total assets is used as the first control variable. This is in line with earlier studies in Indian context such as Sarkar and Sarkar (2000), Kumar (2004), Black and Khanna (2007), Dharmapala and Khanna (2013), Balasubramanian *et al.* (2010), Kota and Tomar (2010) and Kumar and Singh (2012). In above-mentioned studies, it is hypothesized that size has a positive influence on performance of the firm because of various reasons such as diversification, economies of scale and access to cheaper sources of funds. In this study, we have used natural logarithm of total assets as Fsize.

Another control variable considered in various studies in Indian Context (Sarkar and Sarkar, 2000; Kumar, 2004; Kota and Tomar, 2010; Kumar and Singh, 2012) is age of firm, which is calculated by difference between the year of study and the year of incorporation. It is hypothesized that older firms are more efficient than younger firms because of the learning curve and survival bias effects. In this study, natural logarithm of the number of years since the incorporation is considered as Fage.

Financial leverage of the firm has also been used as control variables in several studies (Sarkar and Sarkar, 2000; Kumar, 2004; Ehikioya, 2009; Kota and Tomar, 2010; Kumar and Singh, 2012). It is calculated by dividing total liabilities with total stockholders' equity. A high debt/equity ratio generally means that a company has been aggressive in financing its growth with debt. It is hypothesized that if a firm uses debt to finance increased operations, the firm could potentially generate more earnings than it would have without this outside financing.

Sales growth is used as control variable in the study and is calculated as total sales of the current year minus total sales in the previous year divided by total sales in the current year (Hermalin and Weisbach, 2012).

Independent variables used in the study are different parameters associated with board of directors. Variables used and their measures are indicated in Table I.

The data descriptive and Pearson correlations between variables have been presented in Table II. It indicates a significant relationship between dependent variables Tobin's Q and ROA with most of the independent variables (board characteristics) and also with control variables. In general, it is indicated that performance measures are positively related to duality and negatively related to board independence, busyness of directors, firm size, leverage and sales growth. For every data set, we have run two regressions each with Tobin's Q and ROA as dependent variable.

5.3 Methodology

When we are interested in analyzing the impact of variables that vary over time, fixed effects (FE) model is used. FE explores relationships between predictor and outcome variables within an entity (in present study, this entity is company). Each company may be having its own characteristics/culture that may or may not influence the predictor variables. While applying FE, it is assumed that something within the company may impact or bias the predictor or outcome variables and this is needed to be controlled. Hence, it is assumed that there is correlation between entity's error term and predictor variables. FE is expected to remove the effect of these time-invariant characteristics to enable estimation of net effect of predictor on the outcome variable. In random effects (RE) model, variation across entities (companies) is assumed to be random and uncorrelated with the predictor or independent variables included in the model. This allows time invariant variables to play a role as explanatory variables.

For checking the applicability of suitable model for the study, we applied Hausman test in which null hypothesis is that RE model is appropriate and alternate hypothesis is that the

Serial no.	Variable name	Description	Measurement
Dependent variable			
1	Tobin's Q	Market value of equity + book value of short-term and long-term debt divided by total assets (FA + INV + CA)	Ratio
2	ROA	Operating profit before depreciation and amortization divided by total assets	Ratio; considered as ratio of PBDITA to total assets
Independent variable			
3	Bsize	Number of directors on the board of a firm	Number
4	Bind	% of outside directors of total number of directors	%
5	Bmeet	Number of board meetings in a year	Number
6	Duality	A binary variable; if chairman of the board is also CEO of the company, its value is 0, otherwise 1	Binary number
7	OBUSYD	Average number of directorship/ chairmanship positions in outside companies held by the directors of a company	Number
8	OBUSYC	Average number of committee positions in outside companies held by the directors of a company	Number
9	IBUSY	Average number of board meeting attended by the directors of a company	Number
Control variable			
10	Fsize	Natural logarithm of total assets	Number
11	Fage	Natural logarithm of the number of years since the establishment	Number
12	Lev	Ratio of long-term debt to the total assets	Ratio
13	Sgrowth	Total sales of the current year minus total sales in the previous year divided by total sales in the current year	%

Table I.
Variables used in the model

FE model is appropriate. We obtain significant *p*-values for both the cases, i.e. when Tobin's Q is the dependent variable and when ROA is the dependent variable. Hence, we rejected the null hypothesis and accepted the alternate hypothesis. Thus, between FE and RE models, the FE model is more appropriate for the study.

Next, to check appropriateness between FE and pooled regression model, we conducted Wald test in which null hypothesis is that pooled ordinary list square regression technique (OLS) is acceptable, i.e. the dummies (for companies) have value equal to zero, and alternate hypothesis is that FE is appropriate. We obtain non-significant *p*-values for both the cases, i. e. when Tobin's Q is dependent variable and when ROA is dependent variable, thus failed to reject null hypothesis. Hence, between FE and pooled OLS, pooled OLS is more appropriate for the study.

The reason of the above result may be that in Indian environment, corporate governance and corporate performance are more affected by the general socio, economic and political factors than the company-specific factors. Hence, the intercept value in regression equation appears to be independent of the entity (i.e. company). Further, FE is taking away certain degree of freedom. Thus, pooled OLS regression may be considered more appropriate for the study.

6 Discussion and analysis

6.1 Data descriptive

Performance variable Tobin's Q has mean (SD) 1.90 (2.06), another performance variable ROA has mean (SD) 0.15 (0.10). It reflects the fact that the accounting-based performance measure (ROA) has lesser variability than the market-based performance measure (Tobin's Q). The size of firm in terms of total asset value varies between Rs 872m to Rs 3,677,440m with mean (SD) Rs 101,188m (267,110). The median value is Rs 30,199m. Board size measured by number of directors varies from 2 to 26 with mean (SD) 11.59 (3.56). Board independence measured by percentage of independent directors to the total number of directors varies from 0 to 100 with mean (SD) 46.78 (11.85). Leverage mean (SD) value is 0.22 (0.18), showing that Indian companies depend more on equity rather than debt.

For further analysis, the data are divided in different subsets. As the median value comes at Rs 30199m, companies with asset value of greater than and equal to Rs 30,199m has been termed as large companies and those with asset value less than Rs 30,199m has been termed as small companies. Median value of board size (Bsize) is 11, hence companies with Bsize less than 11 have been termed as small board companies and those with more than and equal to 11 have been termed as large board companies. We have run the regression models first for complete data set and then for each of the data subsets mentioned above.

We have checked the significance of statistical difference between characteristics of small companies and large companies (results are presented in Appendix). It has been found that large companies have significantly bigger board size compared to smaller companies. Bigger board size for larger companies indicates requirement of more number of directors to oversee the increased business size. It is also found that the board of bigger companies meet more often as compared to the board of smaller companies. Duality, i.e. the CEO holding the position of chairman of board of directors, is more in case of smaller companies than the larger companies. It may be because with increasing size of company, the perceived good practice of separating the two roles is being adopted by the companies more and more. Firm performance is also found to be significantly different between larger and smaller companies, with smaller companies exhibiting better performance on both kinds of performance measures, namely, market-based measure (Tobin's Q) and accounting-based measure (ROA).

It is observed that board meetings are happening more in case of bigger board size companies as compared to companies with smaller board. Duality, i.e. the CEO holding the position of chairman of board of directors, is more in case of smaller board companies than the larger board companies. Firm performance is also found to be significantly different between larger board and smaller board companies, with smaller board companies exhibiting better performance on market-based measure (Tobin's Q) and larger board companies exhibiting slightly better performance on accounting-based measure based (ROA).

Regression results: pooled OLS regression results for complete data set and for subsets are presented next.

6.2 Results and analysis

From the regression result presented in Tables III-VII, value of collinearity statistics, i.e. tolerance and variance inflation factor (VIF), is within their acceptable limits (i.e. VIF < 10 and tolerance > 0.1), indicating the absence of multicollinearity problem. Values of Durbin Watson statistic for all regressions are close to 2, indicating absence of auto correlation, which is expected in case of panel data if error terms are related with previous years data.

Table IV. Regression results for small companies

For all data regression (Table III) and for small companies (Table IV), value of coefficient of board independence is negative but non-significant when Tobin's Q is the dependent variable and positive and significant when ROA is the dependent variable. In case of large companies (Table V) and small board companies (Table VI), value of coefficient of board independence is positive but non-significant with Tobin's Q as the dependent variable and positive and significant with ROA (0.001) as the dependent variable. For large board companies (Table VII), value of coefficient of board independence is negative but non-significant when Tobin's Q is the dependent variable.

So, *H1* is supported when performance measure is accounting-based. It indicates that although board independence is affecting the performance of the company, market does not attach value to it. This is giving credence to the theoretical aspect that independent boards do better monitoring function, leading to better firm performance.

For all data regression (Table III), coefficient of number of CEO duality is positive and significant for both the performance measures, Tobin's Q (0.249) and ROA (0.013). In case of small companies (Table IV) and small board companies (Table VI), coefficient of CEO duality is positive and non-significant when Tobin's Q is the dependent variable and positive and significant when ROA is the dependent variable. In case of large companies (Table V) it is reverse, i.e. coefficient of CEO duality is positive and significant (0.194) when Tobin's Q is the dependent variable and positive and non-significant when ROA is the dependent variable. In case of large board companies (Table VII), coefficient of number of CEO duality is positive and significant for both the performance measures, Tobin's Q (0.266) and ROA (0.010).

So, *H2* is validated for all data and for large board companies. It indicates that for large board, it is desired that chief executive officer and chairman positions are separated for better firm performance.

Table VII. Regression results for large board companies

From the regression result of all data presented in Table III, *H3* is not validated as board size is having statistically significant positive coefficient (0.029) in regression equation with Tobin's Q as the dependent variable and significant positive coefficient (0.004) in regression equation with ROA as the dependent variable. Further, it is indicated that board size impacts market-based performance measure (Tobin's Q) more as compared to accounting-based performance measure (ROA). This is in line with results reported by Dwivedi and Jain (2005), who found a positive relationship between board size and Tobin's Q; however, it contradicts the negative relationship observed by Kumar and Singh (2013).

When the regression is run for data subsets (Tables IV Table V), the value of coefficient of board size for smaller companies is negative but non-significant when Tobin's Q is the dependent variable and positive and significant when ROA is the dependent variable. In case of large companies, value of coefficient of board size is positive and significant with both Tobin's Q (0.048) and ROA (0.003) as dependent variables. Thus, *H3a* is not validated.

In case of small board companies (Table VI), the value of coefficient of board size is negative (−0.124) and significant when Tobin's Q is the dependent variable and positive (0.012) and significant when ROA is the dependent variable. In case of large board companies (Table VII) values of coefficient of board size are positive and significant with both Tobin's Q (0.041) and ROA (0.002) as dependent variables. So, *H3b* is supported when the dependent variable is Tobin's Q and not validated when the dependent variable is ROA, i.e. companies with small board and companies with large board show different relationship between board size and performance when the performance measure is market-based, whereas they show similar relationship when the performance measure is accounting-based.

The value of coefficient is positive and significant when ROA is the dependent variable for all cases, i.e. board size is positively related to accounting-based performance measure, and for market-based performance measure, it varies from significantly positive to insignificant to significantly negative under different cases. This is in line with results reported by Kamal Hassan and Saadi Halbouni (2013), who found that board size significantly influences accounting-based performance measure, while none of the governance variables significantly affect firms' market performance. This may be because of the reason that for small companies, market might not attach positive value to the resource dependency theory of having more number of directors, leading to more contact to the outside world. For complete data and for large companies, market-based performance measure is positively associated with the board size, indicating that the resource linkage requirement is being fulfilled by the increased size of the board, thus validating that resource dependency theory.

For all data regression (Table III), coefficient of number of board meeting is positive and significant (0.1) when Tobin's Q is the dependent variable and positive and non-significant when ROA is the dependent variable. In case of small companies (Table IV), coefficient of number of board meeting is positive and significant for both the performance measures of Tobin's Q (0.158) and ROA (0.006), whereas in case of large companies (Table V) and small board companies (Table VI), it is non-significant in both the cases. In case of large board companies (Table VII), the result is similar to all data regression.

So, *H4* is broadly validated in case of Tobin's Q as performance measure, whereas it is only validated in case of small companies when performance measure is ROA. It indicates that number of board meetings send a positive signal to the market and is found to be value-creating.

For all data regression and data subsets, coefficient of internal busyness (IBUSY) is found to be statistically non-significant. So, *H5* is not validated.

For all data (Table III), value of coefficient of external busyness of directors as directors in other companies (OBUSYD) is negative but non-significant when Tobin's Q is the dependent variable and negative and significant when ROA is the dependent variable. For small companies (Table IV), value of coefficient of is positive but non-significant when Tobin's Q is the dependent variable and negative and significant when ROA is the dependent variable. In case of large companies (Table V) and small board companies (Table VI), values of coefficient of OBUSYD are non-significant with both Tobin's Q and ROA as dependent variables. For large board companies (Table VII), value of coefficient of board independence is non-significant when Tobin's Q is the dependent variable and is negative and significant when ROA is the dependent variable.

So, *H6* is supported when ROA is the dependent variable and external busyness of directors is measured in terms of number of directorship positions held in other companies.

For all data (Table III), small companies (Table IV) and small board companies (Table VI), values of coefficient of external busyness of directors as committee members in other companies (OBUSYC) are negative and significant when Tobin's Q is the dependent variable and non-significant when ROA is the dependent variable. In case of large companies (Table V) and large board companies (Table VII), values of coefficient of OBUSYC are non-significant with both Tobin's Q and ROA as dependent variables.

So, *H6* is supported when Tobin's Q is the dependent variable and external busyness of directors is measured in terms of number of committee positions held in other companies. Hence, external busyness of directors perceived by the market is the committee position held by directors in other companies. Thus, it is indicated that when directors held too many outside committee positions, they become overburdened and their involvement in board functions such as monitoring decreases, which leads to decreased firm performance. This is in line with reports by Sarkar and Sarkar (2009), who found that multiple directorships is negatively related to firm performance.

For all data regression (Table III), small companies (Table IV) and small board companies (Table VI), values of coefficient of firm size are negative and significant with both Tobin's Q and ROA as dependent variables. This indicates that for bigger size firms, it is difficult to manage performance. In case of large companies (Table V), value of coefficient of firm size is non-significant with both Tobin's Q and ROA as dependent variables. For large board companies (Table VII), value of coefficient of firm size is non-significant when Tobin's Q is the dependent variable and is negative and significant when ROA is the dependent variable.

For all data regression (Table III), firm age is having significant negative coefficient with Tobin's Q as the dependent variable and non-significant coefficient with ROA as the dependent variable. In case of small companies (Table IV) and small board companies (Table VI), value of coefficient of firm age is negative and significant when Tobin's Q is the dependent variable and positive and significant when ROA is the dependent variable. Negative coefficient in case of regression with Tobin's Q indicates that market is not attaching value to the cumulative learning compared to expected gain from agility of new firm. In case of large companies (Table V) and large board companies (Table VII), the value of the coefficient is non-significant for both ROA and Tobin's Q as dependent variables.

Coefficients of leverage in regression equations is negative and significant for all data and for all the data subsets for both Tobin' Q and ROA as dependent variables, indicating that for Indian companies, cost associated with debt is more compared to the value created by it. It may be because of the reason that for Indian companies, capital is available through internal resources easily compared to external source of capital, particularly debt.

Sales growth as control variable does not seem to impact any of the performance variables Tobin's Q or ROA, as it is not having any of the coefficients significant in regression with either all data (Table III) or in regression with most of the data sets (Table V and Table VI). However, in case of data subsets for small companies (Table IV) and for large board companies (Table VII), values of coefficient of sales growth are significantly positive in the regression with both Tobin's Q and ROA as dependent variables. This may be because smaller companies on growth path show firm value positively related to sales growth. In case of large boards, it may be explained in terms of more monitoring by the board, leading to further value-creation based on the background of previous growth.

7. Conclusions

This paper examines the hypothesized relationship between board structure and firm performance measured by Tobin's Q and ROA for a sample of Indian firms listed at NSE. The results broadly indicate that corporate governance variables affect market-based performance measures (Tobin's Q) more in comparison to accounting-based performance measure (ROA).

H1 states that the board independence would be positively associated with firm performance. From the results, board independence is found positively and significantly related to accounting-based performance measure (ROA) and not related to the market-based performance measure (Tobin's Q). This is in line with earlier studies (Kumar and Singh, 2012; Dey and Chauhan, 2009) that used Tobin's Q as performance measure and found board independence not impacting firm performance significantly. Above finding is a result of the fact that the board independence in India is heavily influenced by the incumbent promoter owners, family owners or private individuals, who are actually responsible for the appointment of independent directors. These independent directors usually go with the management's decision and are not so strong a force to do efficient monitoring.

The finding is also directionally similar to the findings of Jackling and Johl (2009), who found a positive association between firm performance and board independence. However, it contradicts with the findings of Jackling and Johl (2009), when the result is interpreted for different performance measures, namely, Tobin's Q and ROA. Jackling and Johl (2009) found this relationship positive and significant in case of Tobin's Q and not significant in case of ROA. The difference may be ascribed to difference in sample size (180 companies against 391 companies for the present study) and period of analysis (one year, 2005-06, for Jackling and Johl and five years, 2009-2014, for current study). The requirement of compliance to Clause 49 of listing agreement was made mandatory from 1 April 2005. So, the positive effect of corporate governance provisions on firm performance would have reflected in the performance of later years.

H2 states that CEO duality (i.e. role of CEO and chairman of the board of directors vested into one person) would be affecting firm performance negatively. Results indicate that the separation of the position of CEO and chairman of the board is creating value. This is in line with earlier studies in Indian context (Kota and Tomar, 2010; Jackling and Johl, 2009; Ghosh, 2006). This finding supports the importance of monitoring role of the board of directors. Separation of the two roles would avoid the conflict of interest, and consequently, the board of directors would be more efficient in its role of monitoring the behaviour of management including the CEO.

Regarding the relationship between board size and firm performance, different studies have contrasting views. Resource access theory predicted larger boards providing greater access to resources, thereby leading to superior performance; however, it also indicates that if the board size becomes too large, decision-making and working as a group towards strategic goal becomes difficult, leading to inferior performance. Because of difference in monitoring as well as resource requirements amongst different type of companies, board size and performance relationship is also contingent upon size of the company itself. This paper hypothesized that the board size is negatively related to firm performance, and the relation between board size and firm performance is different for different type of companies. Results of this study found that board size is positively and significantly related to ROA, adding credence to "resource access" theory. This finding may be due to the contextual aspect of Indian business environment, where directors are providing linkage to the external resources. We also observed a significant difference between board sizes of smaller and larger companies which may be due to increased monitoring requirements as the company size grows. In case of bigger companies, board meetings were found more frequent compared to smaller companies, confirming increased monitoring requirements.

Board meetings are platforms for discussing the performance and behaviour of management apart from deciding on the strategic directions for the company. Keeping this in view, this paper hypothesized that the number of board meetings is positively related to firm performance. Results indicate that the number of board meeting is positively and significantly related to market-based performance measure, i.e. Tobin's Q. Hence, an increased number of board meetings is found to send a positive signal to market, thus creating value for the firm.

Board of directors perform their monitoring function through their participation in board meetings. This study has defined busyness of directors in terms of their participation in board meetings. So, it is hypothesized that the directors' internal busyness is positively related to firm performance. However, results indicate that the performance is not significantly related to any of the performance measure in all regressions. This may be because of possible complex relationships between number of board meetings and performance in place of assumed linear relationship, thereby making it difficult to estimate. There may also be a possibility of lag effect in this relationship, i.e. the response of board of directors towards poor performance may yield result in the following year (Vafeas, 1999).

Resource dependency theory predicted that multiple positions held by directors would create more resource linkage for firms, leading to superior performance. However, on the contrary, it also predicts that directors with too many outside positions would reduce their effectiveness as far as the monitoring role is concerned. With this view, this paper hypothesized that the directors' external busyness is negatively related to firm performance. The results indicate that the external busyness when measured in terms of number of directorship position held in other companies affects market based-performance measure negatively, and when measured in terms of number of committee positions held in other companies, it affects the accounting-based measure adversely. Thus, overall overburdened directors affect firm performance negatively. This result also indicates that busy directors may not have necessary reputation and networking contacts that are necessary to generate benefits to the company (Jackling and Johl, 2009).

Among control variables, both firm size and firm age are found to have a negative relationship with firm performance, indicating that newer firm with newer technologies and up to a certain optimal size are better able to manage performance. The negative relationship of leverage with firm performance indicates that for Indian firms, it is less costly to manage resources through internal sources than through the debt market. Sales growth has generally been found not related to firm performance.

This study has implications for investors, academicians and policy makers as the findings indicate impact of specific corporate governance variables on corporate financial performance. The study is important for both domestic and foreign investors as it gives an indication to the type of companies (from corporate governance point of view) in Indian context that may give better financial results. Findings also indicate that investors should look for companies with an optimal and diversified board. Relatively smaller companies based on newer technologies may also be chosen by investors for a better return. As an implication, this indicates that if foreign investors in developed economies come with their newer technologies and improved corporate governance practices, it may result into good corporate performance. The literature review done under the study suggests that governance reforms that encourage firms to adopt better governance practices reduce the likelihood of earnings management. The evidences from emerging market enhance our understanding of corporate governance in those economies.

In this study, board independence is found to have a positive relationship with firm performance. Hence, agency theory has been supported by findings of this study. Next finding of the study, i.e. separate positions of CEO and chairperson of the board positively associated with firm performance, is contrary to the stewardship theory. Positive association between size of the board and firm performance indicates support for resource dependency theory. Hence, the study supports agency theory and resource dependency theory.

Few limitations of this study are in terms of methodology and possible omission of some variables. Concerns have been raised about the kind of relationship between board structure and firm performance in various theoretical and empirical studies. It has been indicated that board structure is endogenously determined by firm-specific factors such as scale economies, regulation and the stability of the environment in which they operate (Hermalin and Weisbach, 1991, 2001, Linck *et al.*, 2008). Existence of reverse causality between board structure and firm performance has also been considered by some of the studies, for example, Adams and Mehran (2012). The existence of reverse causality could have been explored using a simultaneous equation framework.

In future, researchers may try to explore governance performance relationship using a wider set of data in terms of number of companies and number of years. Reverse causality may also be studied using simultaneous equation approach. Even study around introduction of major changes in corporate governance regime in India, namely, 2000 (introduction of Clause 49 in the listing agreement), 2004 (introduction of penal provisions in Clause 49), 2010 (recommendations of Murthy committee on audit committee and whistle blower policy) and 2014 (enforcement of new companies act with specific provisions on corporate governance), may give insights into impact of specific governance mechanism on corporate performance in Indian context.

The relationship between corporate governance and financial performance

Evidence from Jordanian family and nonfamily firms

Zaid Saidat, Mauricio Silva and Claire Seaman
Department of Business, Enterprise and Management, Queen Margaret University, Musselburgh, UK

Abstract

Purpose – The purpose of this paper is to attempt to fill a research gap in the relationship between corporate governance mechanisms and financial performance of family and non-family firms' by using a sample of non-financial firms listed on Amman Stock Exchange (ASE) for the period 2009–2015.

Design/methodology/approach – This research employs a quantitative method using data that include corporate governance mechanisms, firm characteristics and financial ratios of a sample of Jordanian listed firms in the ASE over the period 2009–2015. The sample covers all companies that have been part of the ASE during the period including both family and non-family firms, part of total of 228 companies listed on the ASE as of 31 December 2015. The study used accounting-based measures such as return on asset (ROA) and market-based measures such as Tobin's *Q* as proxies for corporate financial performance.

Findings – The study found that board size both in term of Tobin's *Q* and ROA has a negative relationship with the performance of family firms. In non-family firms, there is no systematic relationship with corporate performance. There is a strong relationship between corporate performance and independent directors in non-family firms. In addition, the authors found some evidence for a relationship between performance and independent directors in family firms. Also, results indicated that ownership concentration has an insignificant correlation with corporate performance and in family firms has a negative and significant correlation with Tobin's *Q*. There is a significant relationship between local investors' ownership and corporate performance as measured by Tobin's *Q* in family and non-family firms.

Originality/value – Studies concerned with the effect of corporate governance on firm performance remains comparatively under-researched in Middle East countries and Jordan in particular (Najib, 2007; Omet, 2004; Marashdeh, 2014). Moreover, studies investigating whether the practice of corporate governance has the same impact on family firm performance are still relatively less well known than those when ownership is distributed widely (non-family firms) (Jaggi, Leung and Gul, 2009; Prencipe and Bar-Yosef, 2011). This research is seeking to fill this current gap in Jordan, which is one of the developing countries with an emerging economics that are very poorly represented in the literature.

Paper type Research paper

1. Introduction

There is a growing body of corporate finance literature that supports a relationship between corporate governance mechanisms and financial performance. In particular, in the USA and the Asian experience, there exists a large body of empirical studies with some reporting positive relationship (see e.g. Bebchuk *et al.*, 2004, in the USA; Haniffa and Hudaib, 2006, in Malaysia; Black *et al.*, 2007, in India), and others reported no positive relationship (see e.g. Chidambaran *et al.*, 2008, in the USA; Aksu and Kosedag, 2006, in Turkey; Rui *et al.*, 2002, in China).

The issues of corporate governance and firm's ownership structure are not new, especially publicly traded company usually owned by many shareholders. Since the early work of Berle and Means (1932), corporate governance has focussed on corporations characterised by diffused ownership that results in the shareholder-managers' problem

arising from the separation of ownership and control. Mayer (1997) stated that corporate governance "is concerned with ways of bringing the interests of investors and manager into line and ensuring that firms are run for the benefit of investors". These companies commonly found in developed countries such as the UK and the USA (Gugler *et al.*, 2008).

La Porta *et al.* (1998) argued that the primary conflict in a firm owned by relatively few large shareholders is between the majority and minority shareholders because of the potential for the former to expropriate wealth from the latter. This is especially the case in Arab countries where ownership and control is mostly in the hands of individuals or families. However, Klapper and Love (2004) stated that it is essential for emerging markets to strengthen their corporate governance standards. Singh (2003) suggested that these markets should inspire companies to practice good corporate governance. In addition, according to Saidi (2005) and Najib (2007), the need to understand corporate governance has become more urgent in developing countries, particularly in the Arab region (Saidi, 2005; Najib, 2007).

In Jordan, as in many Arab countries, most companies are concentrated ownership, dominated by the family, where the founder and/or family members usually possess a great many shares of the company and often have a significant impact on the management of the company's operations. Family members usually participate in the management of a firm by holding positions such as chairman of the board of directors and/or senior executive. Previous studies indicate that family firms have different corporate governance from their non-family counterparts (Setia-Atmaja *et al.*, 2009; Navarro and Ansón, 2009). However, studies investigating whether the practice of corporate governance has the same impact on family firm performance are still less well known. Jordan in particular, where the empirical part of this study takes place, the family firms has forms a considerable part of its economy. In fact, most of the literature on corporate governance in Jordan the family firm has received almost no attention (e.g. Al-haddad *et al.*, 2011; Al-Fayoumi *et al.*, 2010; Abed *et al.*, 2012). Taking into the account the significant differences in the characteristics of family firms, the impact of corporate governance on family firms may not be the same as on non-family firms. For instance, according to Carney (2005), family firms are owned and controlled by family members and, therefore, are more able to make independent decisions than non-family firms where ownership is typically more dispersed. Further, the family's control rights influence a firm's assets by providing a source of advantage in scarce environments, the possibility of creating and using social capital and the possibility of generating more opportunistic investment processes (Carney, 2005).

This paper aims to answer the following question: does corporate governance have an impact on the financial performance of companies in Jordan? This paper investigates the effect of corporate governance on financial performance of family and non-family firms in the Jordanian context through descriptive data, *t*-test, correlation and regression analysis.

2. Defining family firms

According to Ang *et al.* (2000), the idea of a family firm is a single family owning at least 50 per cent of the company's stocks. While Faccio and Lang (2002) propose at least 20 per cent of voting rights held by one family, Barth *et al.* (2005) consider control of more than 33 per cent of the company's shares an appropriate definition. On the other hand, Fahlenbrach (2009) and McConaughy *et al.* (1998) classify a firm as family firm if the founder and/or descendants are CEO of the company. Differently again, Claessens *et al.* (2000) and Morck *et al.* (1988) define family businesses as those firms where top positions are held by a family member or direct family related by blood or marriage or indirect family relationship. Lastly, Björnberg and Nicholson (2012) confirms that if the family members own the largest shareholding of the business, and more than one family member holds a top leading position, "the firm identifies itself as a family business".

In this study, the criterion to define a firm as family firm based on "10% cut-off level" was adopted, in line with two important research that are often cited in corporate finance studies (La Porta *et al.*, 1999; Claessens *et al.*, 2000). One of La Porta's (1999) explanations for using the 10 per cent cut-off level is "to provides a significant threshold of votes; and most countries mandate disclosure of 10 per cent, and usually even lower, ownership stakes" (pp. 475-476).

3. Literature review and hypothesis development

3.1 Board structure

One of the most important governance mechanisms is board size as it indicates the participation of a board in company affairs and activities. The number of members on the board indicates the effectiveness in controlling and directing the company (Maztoul, 2014). Florackis (2008) claimed that small board size is likely to be better for coordination and communication. These views are opposed by Epstein *et al.* (2002) and Goshi (2002). who suggested that a board of 16 directors is an optimal number for large companies. Pearce and Zahra (1992) argue that larger boards are more beneficial because they can provide a broader perspective and a better route as of strategic options for the company. With respect to family businesses, Navarro and Ansón (2009) suggests that families may be reluctant to increase the size of the board so as to maintain control, and facilitate communication when making decisions, and thus reduce the problem of free-riding. On the other hand, Ibrahim and Samad (2011) found that larger board size has a significant effect as a device in mitigating agency costs. Hansson *et al.* (2011) pointed out that a large board is a less effective governance mechanism, and thus has an adverse effect on firm performance.

In Jordan, the board of company, whether family or public company should not be more than thirteen and not less than three as specified by the Company of the Assembly, presented at the Companies Law number 22 of 1997.

A further corporate governance mechanism that might improve or reduce firm performance is CEO duality; the same person holds both the CEO and chairman in an organisation. Advocates of separation of the chairman and CEO base their view on the agency theory and argue that the combination of the two positions in the hands of one person can lead to greater agency problems result from an ineffective monitoring of the CEO by the board (Jensen, 1993). Ehikioya (2009) argued that to guarantee the independence of the board, it is strongly recommended to divide the two positions in order to obtain effective checks and balances over the top management behaviour.

CEO duality is more likely within family firms, as the families have the largest shareholding (Bartholomeusz and Tanewski, 2006; Chen *et al.*, 2005). However, Navarro and Ansón (2009) stated that the main role of the board in the family business is to support managers, not to observe them, and therefore CEO duality might not necessarily harmful. In other words, when the CEO and chairman of the board is a family member, it might reduce the severity of conflict of interests, and duality may facilitate family businesses governance. In terms of performance, Cabrera-Suárez and Martín-Santana (2015) found that duality itself does not have any influence on the performance of family businesses, but when there is duality, and a board with a majority of outside directors would be preferable. This means that family commitment, unity of command and unique business knowledge must be accompanied by external advice and a wider range of perspectives. The study confirms the argument of Carney (2005), who stated that management in family business may be at a disadvantage when it comes to general business knowledge, owing to nepotism and difficulties in attracting high-quality, non-family managers. In Jordan, the Jordan Corporate Governance Code (JCGC) was released in 2006 and recommended the separation of the two positions from each other.

One of the main debates in corporate governance concerns independent directors and its ability to control top management and reduce agency problems, in particular the problem of information asymmetry. Monks and Minow (2004) argue that the independent directors are very important in influencing corporate performance. From the agency theory perspective, independent directors are more likely to protect shareholders against any self-serving behaviour by management and act in shareholder interest in a better way compared to non-independent directors thus preventing the eventual expropriation of shareholder wealth (Arosa *et al.*, 2010). Belkhir (2009) argue that the independent directors can help reduce the risk of moral hazard through the oversight role on the managers, and also alleviate the problem of information asymmetries by ensuring disclosure of a wide range of risks and related information to shareholders.

Also, it is suggested that independent directors should function to mediate conflict between majority and minority shareholders and make managers more active through better monitoring, thus improving firm performance (De Andres *et al.*, 2005). Although families may seek to minimise the presence of independent directors, Anderson and Reeb (2004) document that minority shareholders in family firms desire them to be on the board to protect their interests. This can be understandable when, as Bartholomeusz and Tanewski (2006) and Setia-Atmaja *et al.* (2009) all suggest, family firms have less levels of board independence compared to non-family firms. However, Kudlats and McDowell (2015) find that having independent directors would be positively associated with performance in family firms.

According to the Companies Law number 22 of 1997, "at least one third of the board members must be non-executive, to comply with the board committees requirements". Also, JCGC (2006) defined independent directors as "an employee of the Company or receiving a salary there from".

However, only a few studies have examined the impact of the board structure on Jordanian corporate performance. For instance, Al-Manaseer *et al.* (2012) state that board structure such as board size and independent directors have a positive association with Jordanian corporate performance, while Marashdeh (2014) and Alabdullah *et al.* (2014) argue that board structure (including, board size and CEO duality, respectively) have insignificant impact on performance. Marashdeh (2014) further reveals a positive significant relationship between independent board and corporate performance. Based on the above discussion, the following hypothesis is proposed to be tested:

H1. There is a relationship between the size of boardroom and corporate performance.

H2. There is a relationship between the CEO duality and corporate performance.

H3. There is a relationship between the independent directors and corporate performance.

3.2 Ownership structure

Ownership structure is one of the most important factors that may contribute to reducing the severity of agency problems in the company. The unification of ownership and control lead to managers being subjected to less pressure from external investors and other observers who demand accountability and strategic renovation (Carney, 2005). Alchian and Demsetz (1972) stated that ownership concentration has been proposed as an internal mechanism to monitor the behaviour of managers by shareholders to ease intra-company conflict problems. They also argued that this mechanism is important in determining the company's objectives and the extent to which managers are disciplined. Thus, an increase in the equity of ownership gives shareholders a greater incentive to monitor and control managers, which, in turn, increases attention onto raising the financial returns (Holderness, 2003).

Miller and Le-Breton Miller (2006) indicated that the reduction of agency costs incurred due to ownership concentration will lead to more benefits (i.e. savings and extra resources) for a firm and increase value. In such a context, better monitoring of managers translates into lower agency costs (Chen and Yur-Austin, 2007), thus contributing to performance and value creation.

With respect to family businesses as a distinctive type of concentration ownership, the family business and corporate finance literature shows a different impact of concentration ownership on firm performance as compared to non-family firms, whereas some studies suggested several points in a favour of a positive relation between concentration ownership and firm performance in family businesses. According to Aguilera and Jackson (2003), family controlling shareholders seeking the strategic interest of their corporation (e.g. securing a new market or protecting administrative independence) are able to make difficult decisions more effectively. Moreover, families are more concerned with their reputation; family reputation can reduce self-management interests when family members are employed in top management positions, thus facilitating the survival of the company (Denis and Denis, 1994), strengthening the long-term relationship with other stakeholders such as capital providers, customers and suppliers (McVey and Draho, 2005). Generally, reputation can lead to a better firm performance (Zellweger *et al.*, 2012). Thus, the performance of a company is likely to improve in a way that is sustainable in the long term.

In family firms, the importance of concentrated ownership has been examined. For example, Lins (2003) using a sample of family firms drawn from 18 emerging economies, found that ownership concentration positively impacted on firm value. He argued that companies with majority shareholders increase the effectiveness of corporate governance of companies in emerging economies. Al-Ghamdi and Rhodes (2015) studied and tested a sample of 792 firm-years among from 11 industrial groups for the years 2006–2013 and compared family and non-family firms in Saudi Arabia and found that ownership concentration in family firms has a significant positive relationship with the performance. Additionally, the findings revealed that the relationship between ownership concentration and performance in non-family firms was positive although not statistically significant. In case of Jordan, most companies have a higher concentration of ownership (OECD, 2003). In this context, this study will investigate the effect of the concentrated ownership on the performance of family and non-family firms.

Institutional investors are considered as one of the most important external corporate governance mechanisms affecting corporate performance. This is because institutions have different investment goals and decision-making opportunities, as well as the power to monitor manipulations by managers and improve firm performance (Shleifer and Vishny, 1997; Bowen *et al.*, 2008). According to Dong and Ozkan (2008), greater expertise and power of institutional investors leads to more rational decision making by management directly through its ownership or indirectly through the trading of its shares (Gillan and Starks, 2003).

In the context of listed family firms, Le Breton-Miller and Miller (2013) find that institutional investors have a positive effect on the financial performance of family firms. They argue that there is a conformity in several aspects of strategy interests between family firms and those investors, which is related to higher returns on assets. Sacristan-Navarro *et al.* (2011) suggest that increasing institutional ownership can benefit family businesses, as these investors may compete for control, thereby reducing the expropriation of minority shares. However, some papers reveal that the combination of family shareholders and other types of shareholders may not necessarily positively affect the performance of family businesses. For example, Fernando *et al.* (2014) identify that principal-principal problems are more prevalent in family firms. They argue that institutional investors are better able to recognise this problem in family businesses. This can imply that family firms are less attractive to institutional investors which are an increasingly important source of capital. In other words, the conflict problems are harmful to non-family shareholders, so family businesses may not be able to access new sources of capital, especially when they need to expand their investments.

In the case of Jordan, most of the major domestic institutional investors are banks, insurance companies and pension funds such as the Social Security Corporation Investment Unit. Thus, they are a good example of "pressure-sensitive" institutional investors. However, it is suggested that such investors are not capable of playing an effective monitoring role and commonly have significant business relationships with companies. In addition, most companies in Jordan have a higher concentration of ownership (OECD, 2003) and lower degree of investor protection (La Porta *et al.*, 1999). Thus, pressure-sensitive investors are less likely to act as effective monitors than pressure-resistant investors.

In addition, the presence of foreign investors is also important, especially in developing countries, the increased expansion of foreign investors is one of the most important factors in emerging markets. This is due to limited domestic resources to finance investment (Leuz *et al.*, 2009), which leads many emerging countries to liberalise their stock markets, and allowing foreign financiers to invest in domestic firms (Kim and Yi, 2015). As confirmed by the international finance literature, this type of investor contributes to enhancing local investments (Henry, 2000) and boosting financial market development and liquidity (Bekaert *et al.*, 2007). Young *et al.* (2008) stated that the presence of foreign investors is an effective part of governance improvement in emerging economies. They also argued that foreign investors are able to monitor the corporations in a better way than domestic ones because they are "outside the domestic social networks from which the institutional norms of behaviour are generated, and they are therefore more likely to push for transparent deals" (Young *et al.*, 2008, p. 212).

In the context of listed family firms, foreign investors would also avoid family firms with poor profitability and poor corporate governance because investing in such firms is not likely to reach their return on investment benchmark. Specifically, in emerging markets, where law enforcement may be weak, and thus an indication of the presence of several risks such as accounting risks, asset risk and strategic policy risk (Clayman *et al.*, 2011) associated with poor corporate governance. For example, strategy risk refers to the risk that owner-managers may exercise their powers in transactions such as acquisitions and mergers that may not be in the best interests of other shareholders, but that may result in large benefits for the directors/managers, whereas asset risk refers to the risk that the company's assets will be misappropriated by the controlling manager-owners (Clayman *et al.*, 2011).

According to the OECD (2006), Jordan is considered to have one of the highest levels of foreign investment of market capital in the world. In 1995, Jordan has liberalised the Amman stock market, allowing international investors to invest directly in the equity securities of Jordanian firms. This resulted in raising the percentage of non-Jordanian ownership from 38.51 in 2001 to 49.50 in 2016. This increase indicates a positive sign of an effective control and good profitability that foreign investors prefer. Therefore, considering the significant influence of the foreign investors on firm performance, especially in emerging markets, this study will examine the effect of non-Jordanian investors on the non-financial firms that listed in Amman Stock Market for the period 2009–2015.

Based on the above discussion, the following hypotheses are proposed to be tested:

H4. There is a relationship between ownership concentration and corporate performance.

H5. There is no relationship between local investors' ownership and corporate performance.

H6. There is a relationship between foreign ownership and corporate performance.

3.3 Control variables

Firm size. This variable has been used in several previous studies (such as, Cassar and Holmes, 2003; Al-Matari *et al.*, 2012). It has been argued that the firm size variable is likely to have a positive correlation to corporate performance. Joh (2003) suggests that large firms are more likely to have a better opportunity than smaller firms in term of accessing external fund at cheap cost and increase firm value, due to their size. On the other hand, many studies (see e.g. Agrawal and Knoeber, 1996) suggest that small firms are better than large firms because of growth opportunities. The explanation for that is because the small firms are more likely to comply with a strict corporate governance rules in order to a attract investors, and thus more external funds to invest these opportunities and increase profitability (Klapper and Love, 2004).

Empirical studies have found inconclusive results on the impact of company size on the financial performance, but they still agree on linkages between the company's size and performance. Many previous studies have measured this variable by the log of total assets (see e.g. Cassar and Holmes, 2003; Elsayed, 2007). The reason behind using the logarithm is to mitigate heteroscedasticity problems (Aliani and Zarai, 2012). Based on the above discussion, the following hypothesis is proposed to be tested:

H7. There is a relationship between firm size and corporate performance.

Leverage. The relationship between the leverage and corporate performance reached mixed results. A positive impact on corporate performance might take place as a consequence for monitoring performed by lenders. Stiglitz (1985) argue that efficient control over management behaviour is carried out primarily by lenders rather than principals. Jensen and Meckling (1976) state that leverage as an internal corporate governance mechanism can play a vital role in reducing agency problem particularly free cash problems. Leverage was related positively to corporate performance, as observed by Agrawal and Knoeber (1996). Moreover, Ross (1977) point out that highly leveraged firms might be a good signal for the firm to meet large amounts of debt.

Conversely, Stulz (1988) reports that highly leveraged for firms will influence the market value of equities and lead to increase the financial risk. Furthermore, Stulz argue that high level of leakage will slow down the performance of the firm by increasing attention and monitoring of creditors on the firm activities. In addition to that, Myers (1977) argues that the high levels of leverage may adversely affect the performance of the firm in accordance with the problem of lack of investment. This is due to the increase in financial leverage, which would hamper the company’s ability to raise new debt. Similarly, Andrade and Kaplan (1998) expect a negative association between leverage and performance. They argue that firm with higher leverage tend to perform worse than firms with lower leverage.

Based on the above discussion, the current study assumes either a positive or negative association between leverage and corporate performance as is shown in the following hypothesis:

H8. There is a relationship between leverage and corporate performance.

4. Data and methodology

This research employs data that includes corporate governance mechanisms, ownership structure, and firm characteristics and financial ratios of a sample of Jordanian listed firms in the ASE for the period 2009 to 2015. The sample covers all companies that have been part of the ASE during this period. Both family and non-family firms have been included in the sample of Jordanian companies listed on the Amman Stock Exchange (2018). Initially, a total of 228 companies were listed on the ASE as of 31 December 2015. Consistent with previous studies in the area of corporate governance and firm performance (see e.g. Anderson and Reeb, 2003; Al-Fayoumi *et al.*, 2010; Estrin *et al.*, 2009), financial companies have been dropped from the sample because they are subject to a strict set of regulations which are different from companies in other sectors (Chen *et al.*, 2009), and the distinctive features of financial statement and reporting rules make these firms incomparable with those of other companies (Abed *et al.*, 2012).

After the exclusion of financial companies, the data used in this study are subjected to the following criteria: first, we exclude companies from the sample if any of the independent variables needed for the analysis are missing from annual reports that are obtained either through the ASE official website, the SDC archives, the companies' websites or Thomson One database. Second, companies that did not survive on ASE for less than the study period (2009 to 2015) were dropped from the sample. This study used the same criteria used by previous studies (Yermack, 1996; Cheng *et al.*, 2008) to drop the firms that did not survive during the study period (2009–2015), which are not selected firms that have been liquidated, whether voluntary or committed, and not selected firms that acquired or merged with another firm.

This selection procedure reduced the sample from 228 to 103 firms during the period 2009–2015 (representing 85.12 per cent of sample to non-financial firms). Table I presents a description of the study sample after excluding items such as financial companies, missing data, and provides 721 firm-year observations. To conduct our investigation, the criterion to define a firm as family firm based on "10% cut-off level" was adopted. Based on this definition, 56 family firms and 47 non-family firms were selected for this study, providing 392 family firm year observations and 329 non-family firm-year observations.

The data were collected from various secondary sources. First, data related to the corporate governance mechanisms and corporate characteristic (firm age) were manually collected from the annual reports of each firm for the relevant years. Second, data related to the ownership structure (large shareholders and local investors' ownership) were manually collected from the annual reports and the companies' websites, while foreign ownership was obtained from Thomson One database and the ASE Annual Company Guide. Third, firm financial performance variables and data related to firm size and leverage variables were obtained from firms' financial statements obtained from the Securities Depository Centre (SDC).

In this study, the accounting-based measure (return on asset, ROA) has been chosen as a measure for financial corporate performance. The ratio for each year is calculated by dividing the net income by the total assets of the company. In addition, market-based measures Tobin's Q which is calculated as the ratio of the book value of total assets minus

Total number of listed companies on Amman Stock Exchange as in December 2015	228
Less no. of financial firms[a]	107
No. of non-financial firms[b]	121
Less no. of companies with missing data	18
Final sample	103
% of sample to non-financial firms	85.12%
Observations	721

Notes: [a]Financial companies include the following segments: Banks, Insurance, diversified financial services and Real Estate Source: Amman Stock Exchange Annual Reports; [b]non-financial companies include the following segments: Health Care Services, Educational Services, Hotels & Tourism, Transportation, Technology & Communication, Media, Utilities & Energy, and Commercial Services, Pharmaceutical & Medical Industries, Chemical Industries, Paper & Carton, Printing & Packing, Food & Beverage, Mining & Extracting, Tobacco & Cigarettes, Engineering & Construction, Electrical Industries, Textiles, Leather & Clothing, and Glass & Ceramics

Table I. Sample selection producer

the book value of equity, plus the market value of equity to the book value of assets. Prior studies have used Tobin's *Q* and ROA as proxies for corporate financial performance (Anderson and Reeb, 2003; Denis and Denis, 1994). Moreover, the study employs pooled regression with panel data for the model of the study.

Thus, based on the previous discussion, the following model has been developed to analyse the relationship between corporate governance mechanisms and financial performance for both family and non-family firms (Table II):

$$\text{Financial Performance} \sim f\,(\text{Board size, CEO Duality, Independent directors, Ownership concentration, Local investors' ownership, Foreign ownership, Firm size, Leverage}).$$

5. Data analysis

This section shows the analysis of data including; descriptive statistics analysis, independent *t*-test and correlation coefficients matrix among the independent and dependent variables, while the final hypothesis test is based on the analysis of data using multiple regression.

5.1 Descriptive statistics

Table III reports that the minimum value of ROA is −17.3 per cent, while the highest value is close to 14 per cent with an average of 2.92 per cent for the overall sample. As regards to Tobin's *Q*, the figures show that the minimum value of Tobin's *Q* is −0.0128, while the highest value is 0.058, with an average of 0.017 for the overall sample firms.

The statistics reveal that the mean board size for the whole sample of the 103 listed Jordanian companies is 8.14, with a minimum of 5 and a maximum of 13 members on the board. In terms of CEO duality, the mean percentage of CEO duality is 18.1 per cent, which means that 81.9 per cent of Jordanian companies separate the position of the chairman of the board of directors from the CEO lessening the effect of the CEO/Chairman on the board. Regarding the independent directors, we can see in Table III an average of 91 per cent of

Variable	Symbol	Definition
Independent variables		
Board Size	*BOSIZE*	The total number of directors that shape the board
CEO Duality	*CEODUALITY*	A dummy variable takes the value of one if the CEO being chairman, and zero otherwise
Independent Directors	*INDTDIR*	The percentage of independent directors by dividing the number of independent directors by the total number of directors
Concentrated Ownership	*OWNCON*	The total of shares that are owned by shareholders who own 5% or more
Local Investors' Ownership	*OWNLOC*	Total percentage of shares owned by institutional shareholders who have been classified as top-5 largest shareholders
Foreign Ownership	*OWNFOR*	The total percentage of shares (capital) that owned by foreign shareholders
Dependent variables		
Return on Assets	*ROA*	(Net income divided by total assets) multiplied by 100
Tobin's *Q*	*TOBIN'S Q*	This ratio calculated by dividing the equity market value by equity book value
Control variables		
Firm Size	*FSIZE*	Natural logarithm of total assets
Leverage	*LEVERAGE*	Total debt divided by total assets

Table II.
Variables definitions and explanations

Variables	Mean	Min.	Max.	SD	Skewness	Kurtosis
ROA (%)	2.92	−17.3	13.6	5.29	−0.807	6.44
Tobin's *Q*	0.017	−0.0128	0.058	0.033	0.212	1.055
BOSIZE	8.14	5	13	2.201	0.376	2.570
CEODUA	0.181	0	1	0.385	1.651	3.725

Table III. Descriptive statistics for all variables

boards are categorised as "highly independent board of directors". This proportion is above the one third independent non-executive directors' requirement suggested by the JCGC.

The statistics reveal that the ownership of firms in Jordan is highly concentrated with an average of 63.8 per cent. This result is comparable to the 61.96 per cent average concentrated ownership in Saudi Arabian firms reported by Al-Bassam *et al.* (2015) with their sample size of 80 listed firms in the Tadawul Stock Exchange. Furthermore, on average, share ownership by local institutional investors accounts for about 39 per cent of Jordanian firms. Foreign ownership, on average, accounts for only a small fraction (17 per cent) of the shares of the 103 firms in the sample, with a maximum of 90.4 per cent.

5.2 Comparing the means between family and non-family firms

A step to be taken before regression analysis is an independent *t*-test to ascertain whether the differences of means for all variables used in the analysis between family and non-family firms are statistically significant. Table IV presents the means for all selected variables for family and non-family firms. It also presents the mean difference for all data observations, standard error, *t*-test and the *p*-value for the mean differences between family and non-family firms.

Basically, the outcomes of an independent *t*-test inform us of the strength of the association of any two variables. Where the correlation value is closer to 1 or (−1), the two

Variables	Family mean	Non-family mean	Diff-mean	SE	*t*	Sig (two-tailed)
Panel A						
BOSIZE	7.949	8.379	0.431	0.164	2.628	*0.008****
CEODUA	0.232	0.121	−0.110	0.028	−3.869	*0.000****
INDTDIR	0.916	0.911	−0.004	0.006	−0.784	*0.043***
Panel B						
OWNCON	0.654	0.618	−0.035	0.016	−2.196	*0.028***
OWNLOC	0.276	0.521	0.244	0.019	12.33	*0.000****
OWNFOR	0.112	0.233	0.120	0.015	7.604	*0.000****

FSIZE	7.224	7.514	0.290	0.041	6.916	*0.000****
LVEGE	0.293	0.367	0.075	0.160	4.529	*0.000****
Panel D						
ROA (%)	0.049	0.582	0.533	0.395	0.348	0.178
Tobin's *Q*	−0.012	0.532	0.0659	0.003	213.5	*0.000****

Notes: Italics means that the variables are statistically significant based on the differences between variable means, except for ROA (not in italics). *,**,***Significant at 10, 5 and 1 per cent, respectively

Table IV. Comparing the means between family and non-family firms variables are more relevant. The mean difference is calculated by subtracting the mean for the variable in the family firms from the mean for the same variable in non-family firms.

As indicated above in Table IV, all variables are statistically significant based on the differences between variable means except ROA. However, there is statistically significant difference between the means in family firms and the means in non-family firms in these variables. Thus, the null hypothesis is rejected.

The following sections offer a descriptive statistical analysis of these variables in family and non-family firms based on the results in Table IV.

Board of directors. In Panel A, a statistical comparison of board of directors' variables means is made between family firms and non-family firms. The mean for the board size (BOSIZE) for family firms is slightly different from non-family firms, i.e. 7.94 and 8.37, respectively. The reason behind the small size of the board of family firms, suggests Ward (1991), is that family firms prefer smaller boards since the individual commitments are subject to dispersion in larger boards. Navarro and Ansón (2009) states that families may be reluctant to increase the size of the board in order to maintain control, and facilitate communication when making decisions, and thus reduce the problem of free-riding.

Also, CEO duality in family firms can improve firm performance by having the same person hold both the CEO and chairman in an organisation. The table shows that the mean of CEO duality for family firms is 23 per cent, compared to 12 per cent for non-family firms, and the difference is statistically significant at the 1 per cent level. The comparison is consistent with the findings by Bartholomeusz and Tanewski (2006) and Chen *et al.* (2005) that CEO duality is more likely in family firms than in non-family firms.

Regarding independent directors, both family and non-family firms have roughly the same mean percentage, i.e. 91.6 and 91.1 per cent, respectively. The differences are statistically significant at the 5 per cent level, which means that Jordanian firms have a higher percentage of independent directors. Thus, the mean composition of boards having 91 per cent of independent directors' means that Jordanian firms whether family firms or non-family firms tend to have at least seven independent non-executive directors on their board. Hence, the board of directors with more executive directors is more likely to approve board decisions without challenging each other at the expense of shareholder interests, as argued by Fama (1980).

Ownership structure. The data in Panel B of the table refer the differences in ownership structure between family firms and non-family firms. We can note that the average of concentrated ownership in family firms is 65.4 per cent, which is higher than the average concentrated ownership of 61.8 per cent for non-family firms. This is logically acceptable because most equity in family firms is owned by one family. The mean differences are statistically significant at the 5 per cent level.

In contrast, non-family firms have a higher proportion of shareholdings by OWNLOC (local companies and government ownership). On average, 52 per cent of shares in non-family firms are owned by domestic institutional investors compared to an average of 27.6 in family firms and the mean differences is statistically significant at the 1 per cent level. Furthermore, we can notice that in our sample, the mean of foreign ownership in non-family firms is 23.3 per cent, which is higher than family firms, where it is only 11.2 per cent. This implies that institutional investors regardless of whether foreigners or locals prefer non-family firms to family firms when investing their money in Jordanian firms. As explained by Fernando *et al.* (2014), principal–principal problems are more prevalent in family firms. They argue that institutional investors are better able to recognise this problem in family businesses implying that family firms are less attractive to institutional investors who are now an increasingly important source of capital.

Control variables. Panel C reveals that non-family firms on average are slight larger in size, as measured by the logarithm of the total assets, compared to family firms. The natural logarithm transformation is applied to obtain the normality distribution. The mean difference for non-family firms and family firms is statistically significant at the 1 per cent level. According to Al-Haddad *et al.*'s (2011) study, a sample of 44 Jordanian firms listed in ASE over the period 2000–2007. They found that the firm size means reached (7.01). It is indicated from the means of firm size in our sample, where non-family firms are larger than family firms that the size of the firms in general increased through the study period; this means that overall Jordanian firms are growing slowly.

Non-family firms are also comparatively older than family firms with an average age of 22.1 years, compared to 19.3 for family firms. The means of firm size and age suggest that family firms need more time to expand their business from a small independent firm to a business group. The table also reveals the means difference of leverage between family firms and non-family firms. In this study, we measure leverage by the long term debt to total assets proxy. The finding reveals that non-family firms have a higher mean leverage than family firms, i.e. 36.7 and 29.3 per cent, respectively. Hence, we expect higher debts for non-family firms in order to monitor and enhance corporate performance through limiting individual consumption, as Jensen (1986) claimed. While, in family firms, we expect lower debts in order to prevent debt default risk.

Financial performance. Contrary to the findings of significant differences as reported in Table IV, we can see that there is a lack of significant differences in the accounting performance (ROA) of family and non-family firms. In Panel E, the averages of ROA for family firms are 4.90 and 5.82 per cent for non-family firms, respectively, indicating that non-family firms are more gainful than non-family firms. Except for the mean differences in the ROA, the differences in the mean of Tobin's between these two types of firms are statistically significant. However, Tobin's Q for family firms at −0.012 is lower than of 0.532 for non-family firms. Further, we can note that the Tobin's Q mean value is less than 1, in both types of firms, suggesting that the market failed to create good shareholder value. This result largely reflects that the performance measurement correlates with the firm size variable.

5.3 Correlation coefficient matrices

This section presents the correlation between the corporate governance mechanisms and financial performance variables by using the Pearson correlation test (see Tables V–VII). Before regression analysis, the correlation coefficient analysis is conducted to test the relationships between the dependent and independent variables (Rahman and Ali, 2006). Further, it is important in order to check for possible multicollinearity "one-to-one relationship" between corporate performance and the explanatory variables in empirical models. Table VI presents the Pearson correlation coefficients for non-family firms, and Table VII presents the Pearson correlation coefficients for family firms in the study.

The tables state the correlation matrix between the explanatory variables for the full sample, family firms and non-family firms. In general, no multicollinearity is observed between them. Only a few variables reveal relatively higher correlations, but still, do not correlate more than 0.8 or 0.9. In all tables, the findings are jointly significant at a 1 and 5 per cent levels of significance, respectively.

Using the analysis above, Tables VI and VII reveal that the concentration ownership has a significant and positive correlation with ROA, in family and non-family firms, at the 1 per cent significance level. The coefficient indicates that if a family or a small number of shareholders continues to own and keep the firm shares, this will adversely affect the performance of the firm, perhaps because one of the most effective ways to reduce conflicts of interests and maximise value in firms is to increase the proportion of concentrated ownership of the firm's shares, as argued by Ke and Isaac (2007). Local institutional investors are significantly negatively related to performance (Tobin's Q), suggesting that

their ability to control and contribute to strengthening corporate governance is not effective, in family and non-family firms. As for foreign ownership, it is significantly negatively related to Tobin's, in non-family firms. While, there are significant positive correlations between foreign investors' and ROA in family firms, with a value of 0.114. This means that foreign investors have an impact on firm performance.

Tables VI and VII also show that there is a positive correlation between CEO duality and ROA and Tobin's *Q*, in family firms, suggesting that when the positions of CEO and chairperson are in the hands of one person, and that person is likely to participate and assist in the decision-making process. Conversely, the analysis reveals that CEO duality does not influence financial performance of non-family firms. For independent non-executive directors, the correlation analysis further suggests a significant and negative relationship between independent directors and ROA, in family and non-family firms, with correlations of −0.133 and −0.016, respectively, which means that independent directors have a negative influence on performance, which is not expected. However, these results do not reflect the full results of the study, which need to include more comprehensive statistical analyses. On the other hand, these results can be used as a comparator with the conclusion of a collective analysis of all the results of the statistical methods used. These relationships need to be tested again in the multivariate analysis, as many other factors need to be accounted for into.

We can see clearly that there is a negative correlation between leverage and ROA, in family and non-family firms, that shows how efficiently the firm is using its current assets. The correlation values are −0.178 and −0.273, respectively. The tables also reveal that firm size was positively and significantly correlated to performance, at the 1 per cent significant level, in both family and non-family firms.

6. Discussion of regression analysis results

This section explains the main results which were drawn from pooled-OLS regression analysis of the relationship between financial performance as a dependent variable measured by ROA, Tobin's *Q* and corporate governance mechanisms as independent variables comparing family and non-family firms.

The following table presents the overall results for the effect of corporate governance (namely; board of directors, ownership structure and control variables) on financial performance measured by ROA as an independent variable comparing family and non-family firms. The results are jointly significant at 1, 5 and 10 per cent of significance. It should be noted that R^2s for the ROA range from 5 to 38 per cent for family and non-family firms. For table Tobin's *Q*, the R^2s are in the same range, i.e. 9 and 19 per cent for family and non-family firms, respectively.

6.1 Board of directors

As shown in Tables VIII and IX, in family firms, the board size has a negative and significant impact on the performance measured by the ROA, which supports the first hypothesis that there is a negative relationship between board size and corporate performance. This negative relationship indicates that when the board size increases, the performance of the family firms will decrease. This is consistent with previous studies such as Bennedsen, Kongsted and Nielsen (2008) and Ibrahim and Samad (2011). Similarly, however, when financial performance is measured by Tobin's *Q*, the table shows a negative and significant association of the board size with corporate performance. Regarding non-family firms, the results show an insignificant relationship between the size of the board and corporate performance (as measured by the ROA or Tobin's *Q*). Based on this finding, the hypothesis (*H1*) for non-family firms, which stated that there is a negative relationship

between board size and financial performance as measured by ROA or Tobin's Q, is rejected. For family firms, it is partially supported in this study.

Furthermore, Table VIII clearly shows a positive significant relationship between CEO duality and Tobin's Q in the family firms. This finding is consistent with the view that firms in which the CEO and Chairperson roles are combined. Such firms are more likely to have better efficient governance mechanisms, which should contribute to improved performance. Conversely, however, when performance is measured by ROA, the result shows an insignificant relationship between CEO duality and corporate performance. Again, based on our findings, *H2* for family firms, which stated that there is a negative relationship between CEO duality and firm performance ROA or Tobin's Q, is not supported.

The result for independent non-executive directors' percentage shows a negative and significant impact on Tobin's Q in family firms. The possible explanation for this result may be that firms with higher proportions of independent directors are more likely to experience lower performance because independent directors are unfamiliar with the operations of company business, are not full-time workers in the firm, and are unable to understand the complexities and difficulties facing the company. Another possible explanation may be that the appointees may not have the relevant skills and experience as they are appointed because of a prior relationship with family shareholders, and therefore feel obliged to work for them. Furthermore, based on the accounting-based measure, there is an insignificant relationship between independent directors and ROA in family firms. Based on our findings, *H3* for family firms, which stated that there is a positive relationship between independent non-executive directors' and firm performance, is rejected.

In Arab countries including Jordan, the board of directors in family firms are generally controlled by family members. Consequently, the board of directors of such firms are likely to influence firm performance. Regarding non-family firms, the results show a highly positive and significant relationship between independent directors and corporate performance (as measured by the ROA or Tobin's *Q*). Based on this finding, *H3* for non-family firms, which stated that there is a positive relationship between independent directors' and corporate performance as measured by ROA or Tobin's *Q*, is supported.

6.2 Ownership structure

In this sub-section, with respect to family firms, it can be observed from Table VIII that the OWNCON coefficient is negative and highly significant in relation to the Tobin's *Q* performance measure. This shows that when the level of ownership concentration increases, the value of the Jordanian family firms decreases. However, a similar relationship is not significant when corporate performance is measured by ROA. This might be explained by DeAngelo and DeAngelo (2000), who argued that when most of firm shares are owned by family, it motivates them to pursuit their own interests rather than the interest of the firm, at the expense of minority shareholders, and thus the poor performance of these firms. Further, large shareholders (concentrated ownership) also negatively affect the corporate performance by choosing less effective governance mechanisms. For example, where the CEO and the chairperson roles are not split, family shareholders have the motivation to continue with poor internal controls to ease their expropriation of the company resources (Lasfer, 2006). Regarding non-family firms, the coefficient on the variable ownership concentration is always negative but has an insignificant influence on the performance (measured by Tobin's and ROA). The result is consistent with the evidence of Demsetz and Villalonga (2001) and Al-Ghamdi and Rhodes (2015) that ownership concentration has no systematic relationship with corporate performance. In conclusion, *H4* is partially supported in this study and, for that, is failing to reject.

Furthermore, Table VIII also shows that local investors' ownership has a statistically significant at 5 per cent and a negative relationship with corporate performance measured by Tobin's *Q*. This finding does not provide any evidence of the effective role of local investors in Jordan, which is in line with Khanna and Palepu's (2000) suggestion on weak domestic institutional monitoring in emerging markets. Also, the result for local ownership and ROA in family firms is consistent with our expectations, as we find the coefficient is negative and statistically insignificant. Regarding non-family firms, the coefficient on the variable local ownership is always positive and has a significant influence on the performance (measured by Tobin's *Q*). The possible explanation of this positive relationship can be attributed to the investment decisions that taken by some types of companies such as insurance companies and pension funds that may affect the conduct of management. In the case of Jordan, most of the major domestic institutional investors are banks, insurance companies and pension funds, such as the Social Security Corporation Investment Unit. Thus, they are a good example of "pressure-sensitive" institutional investors. However, it is suggested that such investors are not capable of playing an effective monitoring role and commonly have significant business relationships with companies. Thus, pressure-sensitive investors are less likely to act as effective monitors than pressure-resistant investors.

In sum, this study suggests that both family and non-family firms with higher level of local investors' ownership have higher performance. This is shown in the relationship between of local investors' ownership and Tobin's Q in Table VIII. This result suggests that, as local ownership increases, the motivated and efficient to monitor management by domestic institutions increases, which leading to higher performance (McConnell and Servaes, 1990; Shleifer and Vishny, 1997).

Foreign ownership in family and non-family firms indeed has a positive and significant impact on ROA and Tobin's Q in Jordan. This is seen in the positive and statistically significant coefficient on OWNFOR. In this case, there is a relationship between foreign ownership and corporate performance, supporting *H6*. This can be interpreting as: an increase of 1 percentage of the foreign ownership results in a 3 per cent increase in the ROA. A similar relationship is found in family firms when financial performance is measured by Tobin's Q.

6.3 Control variables

Our results as shown above in Table IX, the firm size has a positive and significant relationship with ROA in non-family firms. This variable has been used by many empirical studies (such as Boone *et al.*, 2007; Segarra and Teruel, 2007). These studies confirm that firm performance can vary depending on the size of the firm. For the firm size, an increase in firm's asset base should lead to improved performance and this should be the case if the firm make maximum use of its assets. This positive relationship suggests that larger firms can benefit from economies of scale and scope than those small one (Joh, 2003). Regarding family firms, the firm size has an insignificant relationship with ROA and Tobin's Q.

Tables VIII and IX show that the leverage variable has a negative and significant impact on the performance of firm as measured by ROA in family and non-family firms. Myers (1977) argues that the high levels of leverage may adversely affect the performance of the firm in accordance with the problem of lack of investment. This is due to the increase in financial leverage would hamper the company's ability to raise new debt. This result is consistent with studies. For instance, Tong and Ning (2004) found that that highly leveraged for firms reflect a negative indication that the firm do not have the ability to face future financial risks.

7. Conclusion

The main objective of the study was to examine the relationship between corporate governance mechanisms and financial performance of family and non-family firms in Jordan. The study found that board size both in term of Tobin's Q and ROA has a negative relationship with the performance of family firms. Conversely, the board size in non-family firms has no systematic relationship with corporate performance. There is a strong relationship between corporate performance and independent directors in non-family firms whether corporate performance is measured as Tobin's Q or ROA. In addition, we found some evidence for a relationship between performance and independent directors in family firms. The results support the view that CEO duality is important for family firm performance.

Our results also show that ownership concentration has an insignificant correlation with corporate performance as measured by Tobin's Q and ROA. On the contrary, ownership concentration in family firms has a negative and significant correlation with Tobin's Q. There is a significant relationship between local investors' ownership and corporate performance as measured by Tobin's Q in family and non-family firms. This is in contrast to the findings for ROA in family and non-family firms. However, the findings strongly support the view that foreign investors are positively impact the performance of family and non-family firms.

A B S T R A C T

We examine the role of concurrent information in the striking increase in investor response to earnings announcements from 2001 to 2016, as measured by return variability and volume following Beaver (1968). We find management guidance, analyst forecasts, and disaggregated financial statement line items are more frequently bundled with earnings announcements, and each of these items explains part of the increase in market response. Furthermore, collectively, these concurrent information releases explain a substantial fraction of the increase in market response to earnings announcements since 2001. This is in contrast to the decline in market response to management guidance issued separately from earnings and the much smaller increase in market response to analyst forecasts issued separately from earnings over this time. The findings indicate that information arrival at earnings announcement dates has increased significantly over the past two decades, and that key components of this are increased disclosures by management of guidance and financial statement line items and forecasts by analysts.

1. Introduction

Beginning with Ball and Brown (1968) and Beaver (1968), a large literature documents that earnings announcements have significant information content for investors. Subsequent literature explores whether and how the information content of earnings announcements varies across time and across firms.[1] These studies report an increase in market response to earnings announcements through the 1990's and early 2000's. More recently, Beaver, McNichols and Wang (2018a) document

[1] Studies examining information content of earnings announcements in the 1990's include Francis, Schipper and Vincent (2002a, 2002b), Collins et al. (2009), and Landsman and Maydew (2002). These studies measure information content as the ratio of the squared or absolute value of residual return during the three days around the announcement to the variance or standard deviation of residual returns during the non-announcement period. Ball and Shivakumar (2008) document an increase in their measure of new information at earnings announcements, *Adjusted* R^2, especially for 2004–2006, the last three years in their data.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

a striking increase in the market response to earnings announcements between 2001 and 2011, measured as the variability of stock returns at earnings announcements relative to the variability of stock returns at other times.[2]

This paper examines two questions concerning the surprising increase in relative return variability after 2001: First, is the increase in relative return variability due to more information being released to investors at earnings announcements, and if yes, what is the nature of the information? Second, how does the magnitude of investors' response to earnings announcements over time compare to the magnitude of the response to disclosures on non-earnings announcement days, specifically management guidance and analyst forecasts? If the pattern of increase in relative price response is observed for other significant information events, it could reflect changes in investors' trading behavior or other factors influencing investor response to information rather than changes in the information released at earnings announcements.

Our primary measure of investor response to earnings announcements is a one-day *U*-statistic, hereafter referred to as *USTAT*, which allows us to pinpoint the single-day market reaction to the earnings announcement. This measure reflects the price response to all information released at the earnings date, potentially including information about the income statement, balance sheet and statement of cash flows, as well as management guidance and information released by analysts or others outside the firm. This analysis is motivated by the theory that price revision is increasing in the precision of contemporaneous signals or disclosures, for example as modeled in Holthausen and Verrecchia (1988) and McNichols and Trueman (1994).

Our second measure of investor response to earnings announcements is a one-day abnormal volume statistic, referred to as *AVOL*. This measure reflects the volume response at the earnings announcement date, relative to the volume in the non-earnings report period. As Beaver (1968) notes, price-based tests reflect revisions in expectations of the market as a whole, whereas volume can reflect revisions in individual investors' expectations. The *AVOL* measure can reflect information that affects the investment decisions of individual investors even in the absence of significant price revision, whereas the *USTAT* measure can reflect significant price revision, even if it does not generate substantial trade. Thus, price and volume measures capture different dimensions of the effect of information on investors' equity holdings.

We document a dramatic increase in price revision at earnings dates after 2001, with the mean *USTAT* climbing from 3.42 in 2001 to a peak of 11.70 in our final sample year 2016. This increase is more than twice the magnitude documented in Beaver, McNichols and Wang (2018a) for three-day price reactions, and an order of magnitude greater than the increase documented for three-day price reactions by earlier studies focused on the 1990s. The mean *AVOL* also increases significantly over this period, climbing from 0.85 in 2001 to 1.96 in 2016.

To address our first research question, we examine the relation between our dependent variables, relative return variability and abnormal volume at earnings announcements, and disclosures included in the earnings press release and analyst forecasts released the same day as the earnings press release. Specifically, we examine whether trends in concurrent management guidance, analyst forecasts, and financial statement line item disclosures explain the increase in *USTAT* and *AVOL* over time. These firm-quarter specific measures contain information about expected future earnings, which valuation theory and evidence indicate will affect equity prices and investor trading decisions. Furthermore, substantial prior research documents these are important sources of information to investors.[3]

Our examination of concurrent information establishes several significant findings. First, management guidance, analyst forecasts and financial statement line items are each increasingly disclosed on the day quarterly earnings are announced from 1999 to 2016. The percentage of earnings announcements with concurrent management forecasts increases from 3% to 36%, the percentage of earnings announcements with concurrent analyst forecasts increases from 33% to 70%, and the percentage of financial statement line items disclosed at earnings announcements increases from 23% to 57%. Second, we observe a positive and significant association between our price- and volume-based measures of investor response at earnings announcements and each of these concurrent information items. Third, our multivariate analysis establishes that concurrent management guidance, analyst forecasts, and disclosed financial statement items each have significant incremental explanatory power to each other and to control variables motivated by prior literature, for the magnitude of price and volume response to earnings announcements. Controlling for these information items reduces the magnitude of the time trend by 42%–75% in different specifications, and renders it insignificant in some. Taking the findings as a whole, they indicate that increased disclosure and concurrent analyst forecasts are very substantial factors in the observed increase in investor response to earnings announcements.

To address our second research question, we examine whether the increased investor response to earnings announcements is observed in earnings-related disclosures made by key actors in a firm's information environment, namely management and analysts. Specifically, we examine whether the market response to management guidance and analyst forecasts issued separately from earnings announcements displays an over-time increase similar to earnings announcements. We compare these disclosures to stand-alone earnings announcements to avoid the confounding effects of simultaneous guidance or analysts' forecasts. The market reaction to stand-alone earnings announcements is of smaller magnitude than the average of all earnings announcements, but exhibits the same increasing pattern over time. In contrast, the market reaction to

[2] Due to availability of time stamp data, the sample period for our study begins in 1999. We replicate Beaver McNichols and Wang (2018a)'s finding of a significant increase in information content from 2001 to 2011, and find it continues in 2012–2016. We will refer to the increase over our sample period or after 2001, though we note that information content of earnings is essentially flat in years 1999, 2000 and 2001, increases in 2002–2006, decreases in 2007–2009 and then increases through 2016.

[3] See Beyer, Cohen, Lys and Walther (2010) for a review of the literature on factors influencing the informational role of these disclosures.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

stand-alone management guidance declines over the sample period, and the market reaction to stand-alone analyst forecasts increases only slightly. Thus, the considerable increase in *USTAT* at earnings announcements is not observed for earnings information released by management and analysts separately from earnings announcements.

Our paper makes several contributions to the literature. First, we propose and find that concurrent information plays a substantial role in explaining the increase in investor response to earnings announcements after 2001. Understanding the cause of the increase in price revision and volume at earnings announcements is of considerable importance given the sizable increase over this period, and relative to prior years. The concurrent disclosures and forecasts we examine explain from 42% to all of the time trend in increased investor response, depending on the measure of market response. In addition, financial statement line items alone contribute half of this explanatory power. Thus earnings announcements are increasingly significant to investors as a source of information and a significant fraction of the increase is associated with greater disclosure of financial statement information.

Second, in contrast to earlier research, we are able to examine the effect of financial statement line item disclosures in the earnings press release for a comprehensive sample. We document that income statement and balance sheet line item disclosures have explanatory power for the increase in all our market response measures, and statement of cash flow line items have explanatory power for the increase in several. These findings suggest that the financial statement disclosures are an important source of new information to investors, even after controlling for the earnings surprise, guidance by management, and forecasts by analysts.

Third, we document a decline in the market response to management guidance over time and relatively little increase in the market response to analyst forecasts disclosed outside of earnings announcements. These findings affirm that the increase in market response at earnings dates is distinct relative to the response to two prominent disclosures of earnings-related information.[4]

Fourth, our study documents a number of empirical regularities related to the increase in market response to earnings announcements we expect are of interest to accounting researchers. We document the behavior of the numerator and denominator of the *USTAT* and *AVOL* ratios, and find the increase in the ratio reflects response at earnings announcements that has changed disproportionately to the response in non-earnings announcement periods. We conduct extensive specification tests and find that our primary results are upheld. These tests include generalizing the relation between the numerator and denominator of the *USTAT* and *AVOL* ratios to allow for a slope different from 1, and examining two alternative measures of market response, adjusted R^2 and a 3-day rather than 1-day *USTAT*. These results provide assurance that our overall findings are not sensitive to the choice of empirical measure. Collectively, our findings indicate that the marked pattern of increased relative price revision at earnings announcements since 2001 reflects increased information content of earnings press releases and concurrent analyst forecasts, and suggest new avenues for exploration.

The remainder of the paper proceeds as follows. Section 2 discusses relevant literature and the motivation for the questions we address. Section 3 discusses the research design and our measures of market response and concurrent information. Section 4 presents descriptive statistics for our sample. Section 5 presents and interprets our findings and Section 6 concludes.

2. Related research

2.1. Prior literature

2.1.1. Changes in the information content of earnings

As noted in the introduction, Landsman and Maydew (2002), Francis, Schipper and Vincent (2002a), Collins et al. (2009), and Ball and Shivakumar (2008) examine whether the information content of earnings announcements has increased over time and explore potential explanations for this trend. These studies were motivated by the concern that financial statement information was largely preempted by other information sources and increasingly irrelevant due to measurement concerns. Each of these studies innovated in the questions asked and the design of their tests. In the Internet Appendix, we discuss key features of these studies and their primary inferences, which motivate some of our research design choices. Given the substantially greater current availability of data and computing power, none of our comments are intended as criticism of these earlier studies.

In the spirit of this earlier literature, Beaver, McNichols and Wang (2018a) examine the time trend of price response to earnings announcements from 1971 to 2011. Our earlier study finds that the three-day *U*-statistic at earnings announcements after 2001 is significantly greater than before 2000, and increases substantially from 2002 to 2011. Our earlier study further explores the cross-sectional relation between *U*-statistic and firm-specific factors, and documents significant positive associations with firm profitability, size, and analyst coverage. After controlling for these factors and variables suggested by prior literature, the coefficient on the time trend decreases only slightly, indicating these firm-specific attributes have very little power to explain the increase in stock price revision at earnings announcements.

[4] We believe researchers interested in voluntary disclosure will want to take account of these patterns in future research. Research on disclosure often assumes behavior is consistent over time, and analyzes samples pooled over many years. Future research on voluntary disclosure may further explore the causes for pattern we document, and at a minimum, design tests that take the decline in market response to management guidance into account.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

2.1.2. Management guidance, analyst forecasts and financial statement disclosure

Our study extends these prior studies by examining the role of three concurrent information releases in the increase in investor response to earnings announcements after 2001: management guidance, analyst forecasts and financial statement line items.[5]

An extensive literature documents that management forecasts are a significant source of information to investors. Furthermore, Anilowski et al. (2007) and Rogers and Van Buskirk (2013) find that firms are more likely to issue management guidance concurrent with earnings post-Reg FD than pre-Reg FD. They hypothesize that the Reg FD restriction against selective disclosure motivated managers to bundle guidance with earnings announcement conference calls so as to communicate with analysts in public venues (Rogers and Van Buskirk, 2013). It is therefore plausible that the increase in bundling of management forecasts at least partially explains the post-2001 increase in investor response to earnings announcements.

The second concurrent information source we examine is analyst forecasts. Analysts serve as information intermediaries and play an important role in acquiring and disclosing information, leading to its incorporation into price. Lang and Lundholm (1996), Francis, Schipper and Vincent (2002b) and Frankel et al. (2006) each provide evidence of a positive association between the informativeness of earnings and analyst coverage and forecasting behavior. The positive relation could occur because analysts' demand for information causes firms' financial reporting and disclosure to be more informative, or because analysts choose to issue forecasts for firms whose financial reporting is more informative. It could also occur because analyst forecasts facilitate more rapid dissemination or processing of earnings information, or because analysts augment the information provided by management. For each of the above reasons, we expect that analyst forecasts issued concurrent with earnings could be associated with greater price response on earnings announcement dates.[6]

The third form of disclosure we examine is concurrently disclosed financial statement line items. Prior studies by Hoskins, Hughes, and Ricks (1986), Livnat and Zarowin (1990), Chen et al. (2002) and D'Souza et al. (2010) find that line item disclosures in earnings press releases contain value-relevant information. However, the studies of Francis, Schipper and Vincent (2002a) and Collins et al. (2009) leave open the question of how these disclosures relate to the increase in market response to earnings announcements over time, and particularly in the post-2001 period. With the benefit of a large sample and comprehensive data on financial statement line item disclosures in earnings press releases, we have the opportunity to examine the informational role of these disclosures in the current information environment. Furthermore, we can assess this after controlling for contemporaneous management guidance, analyst forecasts and a number of control variables earlier studies did not include.

Our second research question explores whether investor response to management guidance and analyst forecasts issued separately from earnings announcements exhibits the increase we observe for earnings announcements. Prior literature establishes that management and analysts' forecasts issued outside of earnings announcements are key sources of accounting-related information. To the extent the pattern we observe at earnings announcements is common to these information events, the increase in *USTAT* and *AVOL* at earnings announcements may reflect market-wide changes in how investors respond to information, rather than an increase in relative informativeness of earnings announcements.

2.2. Recent literature

Several recent papers examine the informativeness of accounting disclosures after 2001. Barth Li and McClure (2018) examine the value relevance of accounting information over the last five decades, and document that the ability of earnings to explain price levels has declined but that this decline is offset by increased explanatory power of balance sheet, cash flow and other financial statement information. Nallareddy, Sethuraman and Venkatachalam (2018) provide complementary findings, documenting that the ability of cash flows to predict future earnings has increased over the 1989–2015 period.

Three recent studies are motivated by the increase in information content documented by Beaver, McNichols and Wang (2018a). Hand, Laurion, Lawrence and Martin (2018) propose and conclude that increased availability of analyst forecast data feeds explains the increase in price revision activity at earnings. They examine the explanatory power of a substantial array of line item forecast errors, and find in some specifications that the time trend in information content is fully explained.

Thomas et al. (2018) draw on the patterns we document in this paper for the *USTAT* and its numerator and denominator. They relate the decline in return variability in the denominator of *USTAT* to recent literature in finance (e.g. Brandt et al., 2009; Bartram et al., 2018) that aims to explain the decline in return variability overall. Thomas, Zhang and Zhu (2018) characterize the role of trading noise in each component and its effect on the *USTAT* ratio. They also derive conditions for changes in normal information arrival and trading noise to increase the *USTAT*.

Drawing on the findings of Beaver, McNichols and Wang (2018a, 2018b), Shao et al. (2018) apply the Ball and Shivakumar (2008) adjusted R^2 measure to explore the increase in information content, and the role of regulation, information leaks, sample composition, preemption of earnings from other disclosures and concurrent disclosures. They argue that regulatory

[5] For ease of exposition, we will refer to these concurrent items as concurrent disclosures or concurrent information. While disclosure often connotes communication from management, our use of concurrent disclosures will include forecast releases from analysts as well as management guidance.

[6] A countervailing force could prevail if the issuance of analyst forecasts at earnings dates is associated with greater preemption by analysts of earnings information in the pre-announcement period.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

changes implemented around 2004 are a primary factor in the increase in information content. We believe these papers are complementary to ours, applying a variety of different research designs to further explore the patterns documented in our earlier study. We further discuss how these studies compare to ours in methods and conclusions in the Internet Appendix.

3. Empirical methodology

3.1. Measures of the information content of earnings announcements

Our main measure of the information content of earnings announcements, the 1-day U-statistic (*USTAT*) captures the magnitude of the squared residual return on the date of the earnings announcement, hereafter the testing period TP, to the variance of residual returns during the non-announcement period, hereafter the estimation period EP. A key advantage of the 1-day window is that it allows us to align the return response to earnings with time-stamped disclosures that are released in the 1-day window.[7] We are thus able to identify the disclosures occurring as prices are responding with a high degree of accuracy.

For each quarterly earnings announcement for firm *i* (day 0), the estimation period, EP, is defined as the period from 130 to 10 days prior to the earnings announcements and days 10–130 days after the announcement. We estimate the market model with daily stock returns in EP, obtain estimates of the intercept and slope coefficient, a_i and b_i, and calculate the residual returns and variance $Var\mu_i$. We then use a_i and b_i to calculate the residual return $\mu_{i,t}$ in TP, and construct *USTAT* as follows:

$$USTAT_{i,t} = \frac{{\mu_{i,t}}^2}{Var\,\mu_i}$$

We utilize time stamps of earnings announcements from Bloomberg, *IBES*, and RavenPack. If earnings are released after normal trading hours, we define the earnings announcement day to be the next trading day. In a procedure to be explained shortly, we also apply the same estimation approach for each “as if” earnings announcement randomly selected from the non-report period. Following Landsman and Maydew (2002) and Beaver, McNichols and Wang (2018a), we aggregate quarterly earnings announcements into calendar years based on the dates of earnings release, and then calculate the mean of *USTAT* for each calendar year.

3.1.1. Development of the nonparametric distribution for USTAT

To generate a sampling distribution under the null hypothesis that earnings announcements do not have incremental information content, for each quarterly earnings announcement, we randomly select a day during its non-report or estimation period. That day is treated as if it were an announcement day. We then calculate *USTAT* in the same manner as the actual earnings announcement, and obtain the mean and median of *USTAT* for that sample of randomly chosen announcement dates. Repeating the procedure 1000 times produces a sampling distribution, which is then compared with the values obtained for the actual earnings announcements.[8]

3.1.2. Ball and Shivakumar (2008) R^2 measure

We also explore the sensitivity of our findings to the Ball and Shivakumar (2008) measure of information content. For each calendar year, we run regressions of calendar-quarter stock returns on quarterly earnings announcement-window returns, and the adjusted R^2 measures the proportion of information incorporated in quarterly returns that arrives on the quarterly earnings announcement day. Similar to *USTAT*, the adjusted R^2 does not require a specific earnings expectation model. We define the earnings announcement window as the one-day window based on Bloomberg, *IBES*, and RavenPack earnings time stamps. Following Ball and Shivakumar (2008), we remove firm-quarter observations with fewer than 60 trading days in a calendar quarter. Under the null hypothesis that earnings announcements do not have incremental information, the R^2 is expected to be 1.67% (100%/60) for the one-day announcement window.

3.1.3. Abnormal trading volume (“AVOL”)

Following Beaver (1968), Cready and Hurtt (2002) and Landsman and Maydew (2002), we create a volume-based measure *AVOL* to capture the information content of earnings announcements. The numerator is the difference between shares outstanding-scaled trading volume on the earnings announcement day (day 0) and average shares-outstanding scaled trading volume in the non-announcement period (day-130 to day-10, day+10 to day+130). The denominator is the standard deviation of shares-outstanding scaled volume in the non-announcement period. Under the null hypothesis that earnings

[7] Because the response to earnings announcements largely occurs in the first day following the announcement, 3-day measures include returns for two days that are largely noise.

[8] Drawing the randomly chosen announcement date from the estimation period for each earnings announcement ensures that the randomly chosen date is from approximately the same calendar period as the actual earnings announcement date. Given that our sample is drawn over 18 calendar years, this procedure seems preferable to allowing the randomly chosen announcement date to occur at any time in the firm's history.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

announcements do not have incremental information, *AVOL* should be zero. Similar to our price-based measures, we adjust our volume measures for after-hours earnings announcements.

3.2. Components of USTAT and AVOL

To analyze the intertemporal change of *USTAT* and *AVOL*, we first decompose the measures into the numerator and the denominator. The *USTAT* numerator, *USTAT_NM*, is the squared residual return on the date of the earnings announcement, and the denominator, *USTAT_DN*, is the variance of residual returns during the non-announcement period. The *AVOL* numerator, *AVOL_NM*, is the shares outstanding-scaled trading volume on the date of the earnings announcement less the shares outstanding-scaled trading volume in the non-announcement period, and the denominator, *AVOL_DN*, is the standard deviation of shares outstanding-scaled trading volume during the non-announcement period.

3.3. The relation between USTAT, AVOL and other variables

We examine the association between our dependent variables, *USTAT* and *AVOL,* and several variables, including time, management guidance, analyst forecasts, and financial statement line items. *T* is a trend variable that takes values from 1 to 18 for calendar years from 1999 to 2016. *GUIDANCE* is an indicator variable that is equal to one when management guidance is issued on the earnings announcement date and zero otherwise. *AF* is an indicator variable that is equal to one when any analyst forecast is issued on the earnings announcement date and zero otherwise. Following D'Souza et al. (2010), we collect financial statement line items disclosed in earnings press releases from Compustat Snapshot. *FS* is the percentage of financial statement items disclosed in the earnings announcement. *IS [BS] {SCF}* is the percentage of income statement [balance sheet] {cash flow statement} items disclosed in the earnings announcement. Appendix 2 provides further details.

Following prior literature, we also include several control variables.[9] *LOSS* is an indicator variable that is equal to one when *PTEBS* is negative and zero otherwise, where *PTEBS* is the sum of Net Income before Extraordinary Items, Tax Expenses, and Minority Interest before Special Items. *CV* is the market capitalization value of the firm's common stock at fiscal quarter end from Compustat. Following Atiase (1985), we take the natural log of *CV*, *LCV*, as a proxy for size. Our measure of analyst following, *NUMESTQ,* is the number of analysts making forecasts of the upcoming quarterly earnings at fiscal quarter end, and is drawn from the *IBES* analyst forecast database. For firm-quarters that are not in the *IBES* database, we assume zero analyst coverage. *FIN* is an indicator variable that is equal to 1 when the four-digit SIC code is between 6000 and 6999 and 0 otherwise. *LAG* is the number of days after the end of the fiscal quarter that earnings are announced. *NONDEC31* is an indicator variable that is equal to 1 for firm-quarters with Non-Dec 31 fiscal year-ends and 0 otherwise. Following Collins et al. (2009), *ABSFE_ST* is the absolute value of *Unexpected Earnings*. *Unexpected Earnings* is measured as the difference between IBES realized street earnings and IBES median consensus earnings forecast at fiscal quarter end, scaled by price (IBES).

3.4. The market response to earnings announcements and other information events

To compare the information content of earnings announcements to that of management guidance and analyst forecasts, we obtain the time stamps of management guidance and analyst forecasts from *IBES*, adjust for after-hours announcements, and create one-day *USTAT* measures. For multiple analyst forecasts issued on the same day, we count them as a single analyst-forecast event. We then separate the management guidance (analyst forecast) events into three portfolios based on their time stamps: Guidance (Forecast) Bundled with Earnings, Stand-Alone Guidance (Forecast), and Stand-Alone Earnings. The Bundled with Earnings (Stand-Alone) portfolios includes disclosures issued (not issued) on the same day as earnings announcements. The Stand-Alone Earnings portfolio includes earnings announcements without either concurrent management guidance or analyst forecasts. We calculate the mean and median *USTAT* of the above portfolios to compare how prices respond to earnings announcements, management guidance and analyst forecasts over time.

4. Sample properties

We start with the universe of firms listed on the NYSE, AMEX, and NASDAQ markets for which quarterly reporting dates are available from Compustat for calendar years 1999–2016. This results in an initial sample of 407,718 firm-quarter observations. We next match this sample with Bloomberg, *IBES*, and RavenPack to obtain a list of firm-quarter observations with earnings announcement time stamps. We include observations for which there is agreement across sources.[10] For after-hours earnings announcements, we use day +1 as the earnings announcement date. For each quarterly earnings announcement included, we require that return data are available for the earnings announcement date, and that there are at least 40 trading

[9] Relevant studies motivating our choice of control variables include Landsman and Maydew (2002); Francis, Schipper and Vincent (2002a); Collins et al. (2009) and Beaver, McNichols and Wang (2018a).

[10] We provide further details on the time stamp data and its effect on our sample in Internet Appendix Table IA 1.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

Table 1
Sample summary.

Compustat Observations from 1999 to 2016	407,718
Less observations for which no time stamps are available	83,733
Less Observations with fewer than 40 days in the non-announcement period	835
Number of observations for which *USTAT* can be measured	323,060
Less observations missing data on:	
Analyst forecasts	73,575
Financial statement line items	46,173
All other variables	185
Number of observations for multivariate regression analyses	203,127

Our initial sample includes all 407,718 Compustat earnings announcements (EA) issued in calendar years 1999–2016. We then intersect Compustat data with three sources that have both dates and time stamps: IBES (1999–2016), Bloomberg (hand-collected from 1999 to mid-2013) and Ravenpack (2000–2016). We require that the earnings announcement day be corroborated by each source when multiple sources of time stamps are available. For further details about the sources used to identify the time of the earnings release, see Internet Appendix Table IA.1. For earnings announcements issued after-hours, we use the next trading day as the earnings announcement day. After excluding 83,733 observations without time stamp data and 835 observations with fewer than 40 trading days in the non-announcement period, our data set includes 323,060 observations with data for *USTAT*. The final sample with data on analyst forecasts, management guidance, financial statement line items and control variables for multivariate regression analyses includes 203,127 firm-quarter observations.

days with nonzero returns in the estimation period. We have the same requirements for each simulated non-report earnings announcement. These steps result in a sample of 323,060 quarterly earnings announcements for which we can calculate *USTAT,* as detailed in Table 1. For the additional hypotheses, we impose additional restrictions on the sample to ensure each firm-quarter observation has data for the required variables.[11]

5. Empirical results

5.1. Initial evidence

This section presents initial descriptive evidence on the behavior of our measures of investor response to earnings announcements, and their association with concurrently issued guidance, financial statement line items, and analyst forecasts. To minimize the potential effect of selection due to database coverage, management disclosure and analyst coverage decisions, we present this descriptive evidence using all observations with the required data for each comparison. Our multivariate tests follow, using the sample for which all variables can be measured.

5.1.1. USTAT as a measure of investor response to earnings announcements

Fig. 1 Panel A provides evidence concerning the impact of adjusting for after-hours earnings announcements. The figure shows the mean of abnormal return volatility before and after adjustment for after-hours earnings announcements. The mean day 0 *Unadjusted USTAT* is 4.08, which is slightly less than the mean day +1 *Unadjusted USTAT* of 5.05; after adjustment, the mean day 0 *USTAT* is 7.59, which is four times greater than the mean day +1 *USTAT* of 1.72. By adjusting for after-hours earnings announcements and thus measuring returns over the period in which the earnings are announced, the average *USTAT* increases by 86%. Consistent with Berkman and Truong (2009), the findings document the importance of incorporating time stamp information when measuring investor response to information, and establish that the response to earnings information occurs primarily on day 0. For this reason, we base our tests on one day announcement measures.[12] We note also that both the adjusted and unadjusted *USTAT* measures lie substantially above the hypothetical value of *USTAT* under the null hypothesis that earnings announcements do not convey incremental information content.

[11] For our analysis using the Ball and Shivakumar (2008) adjusted R^2 measure, we require each firm-quarter have at least 60 daily return observations in the calendar quarter; the resulting sample size is 319,385 firm-quarter observations. For our analysis on the volume-based measure *AVOL*, we require each firm-quarter to have at least 40 days with nonzero volume data in the estimation period; the resulting sample size is 322,981. For our analysis on financial statement items, Compustat Snapshot coverage is required, and the resulting sample size is 248,412 firm-quarter observations. For our multivariate regression models, we require included firm-quarters to have all required variables, resulting in a sample size of 203,127 observations. For the analyses of management guidance and analyst forecasts, we require the observations included to have non-missing time stamps from IBES, non-missing return data from CRSP, and at least 40 trading days with nonzero return data in the estimation period. The subsamples of Guidance Bundled with Earnings, Stand-Alone Guidance, Forecast Bundled with Earnings, Stand-Alone Analyst Forecast, and Stand-Alone Earnings have 102,591, 87,091, 179,004, 1,944,828, and 124,791 observations, respectively.

[12] We assess the robustness of our findings to measuring the *USTAT* over 3-day windows, and find none of our conclusions about explanatory factors are affected (Table IA 6). We also assess whether our findings of elevated day +1 *USTAT* occurred in earlier years, in Internet Appendix Figure IA 1. In analysis looking back to 1970, we find an elevated day +1 unadjusted *USTAT* began in the 1990's, consistent with greater after hours earnings announcements around that time.

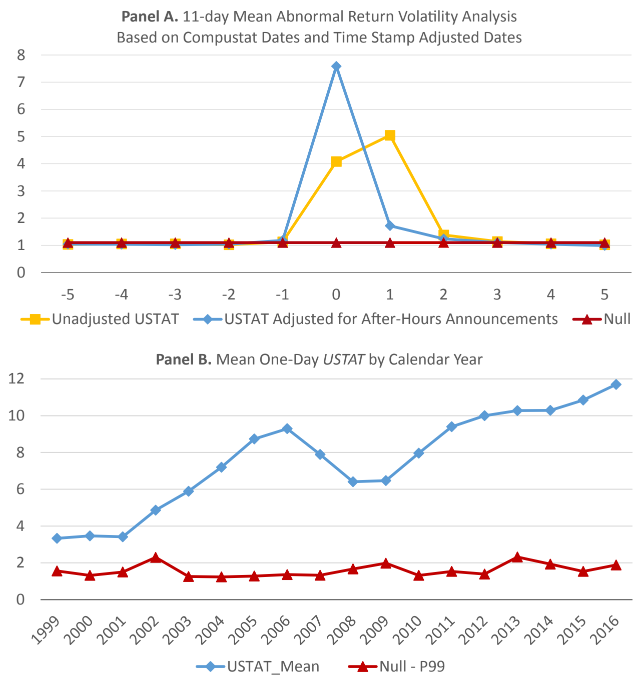

Fig. 1. The figure in Panel A plots mean abnormal return volatility over the 11-day window centered around the earnings announcement day as indicated by Compustat dates ("*Unadjusted USTAT*") and dates adjusted for after-hours earnings announcements ("*USTAT*"). The event sample includes 323,060 quarterly earnings announcements. The figure also plots the mean abnormal return volatility under the null hypothesis that earnings do not have information content. The figure in Panel B plots the mean one-day and three-day information content. *USTAT* is the one-day U-statistic based on announcement dates adjusted for after hours announcements using time stamps. *Null - P99* is the 99th percentile of the mean of *USTAT* for dates randomly drawn from the non-announcement period. Table 1 describes the adjustment for after-hours announcements using time stamps.

Fig. 1 Panel B shows the relative price response to earnings announcements from 1999 to 2016. To allow an assessment of statistical significance of the earnings date *USTAT* measures, it presents the mean 1-day *USTAT* and the 99th percentile of the sampling mean distribution for the 1-day non-announcement period each year, labeled *NULL-P99.*[13] The mean *USTAT* values are above the 99th percentile in each of our 18 sample years. There is a marked increase in the mean *USTAT* as was seen for the 3-day *USTAT* in Beaver, McNichols and Wang (2018a) in 1999 through 2011; this increase is followed by further increases in 2012 through 2016.

Table 2 presents evidence of the increasing information content numerically. It reports the mean *USTAT* by year for each event period, along with the 99th percentile of the sampling distribution for the non-announcement period. Regarding the time trend in the *USTAT*, an increase is evident from 1999 to 2016. The mean *USTAT* is 3.33 in 1999 and climbs to 11.70 in 2016. It is also clear from Table 2 and Fig. 1 Panel B that the increase is not monotonic: from 2006 to 2009, the mean *USTAT* declines from 9.29 to 6.41.

Fig. 2 displays the adjusted R^2 from regressions of calendar-quarter returns on one-day announcement returns, pooled by calendar year. The figure compares these values with the benchmark R^2 of 1.67%, under the null hypothesis that earnings announcements do not have incremental information content. Similar to our *USTAT* findings, the figures display evidence that earnings announcements convey more information than would be expected under the null in each of the years from 1999 through 2016. The intertemporal trend of adjusted R^2 is generally similar to that of *USTAT* in Fig. 1 Panel B. As Table 2 indicates, the adjusted R^2 increases from 4.30% in 1999 to 13% in 2016, and decreases from 15.63% in 2007 to 8.33% in 2008. Our findings parallel those of Ball and Shivakumar (2008), who note the increase in adjusted R^2 for years 2004–2006. Our findings for the subsequent 10 years document the decline in the adjusted R^2 measure during the financial crisis and the subsequent increase to substantially greater levels than 1999–2003. Shao, Stoumbos and Zhang (2018) document a similar pattern using annual

[13] The 1-day *USTAT* is substantially greater than a 3-day *USTAT* we present in the Internet Appendix, Figure IA 2 and Table IA6, consistent with the evidence in Panel A that the price response to earnings announcements largely occurs during the trading day immediately following the earnings announcement.

Table 2
The information content of earnings announcements by year.

Year	*Nobs*	*USTAT*	*Null-P99*	*USTAT_NM*	*USTAT_DN*	*ADJ R^2*	*AVOL*	*AVOL_NM*	*AVOL_DN*
1999	17,304	3.33	1.56	0.0061	0.0021	4.30%	0.88	7.82	10.47
2000	19,975	3.47	1.32	0.0085	0.0031	4.58%	0.80	7.31	10.33

Nobs is the number of observations with data for *USTAT*. *USTAT* is the mean one-day U-statistic using dates adjusted for after-hours announcements based on time stamps. *Null - P99* is the 99th percentile of the mean of *USTAT* drawn from the non-announcement period. *USTAT_NM* and *USTAT_DN* are the numerator and denominator of *USTAT* respectively. *ADJ R^2* is the estimated adjusted R^2 from the quarterly regression of calendar-quarter returns on one-day quarterly earnings announcement returns. The number of observations for *ADJ R^2* is 319,385. *AVOL* is the mean one-day abnormal trading volume using dates adjusted for after-hours announcements based on time stamps. The number of observations for *AVOL* is 322,981. *AVOL_NM* and *AVOL_DN* are the numerator and denominator of *AVOL* respectively.

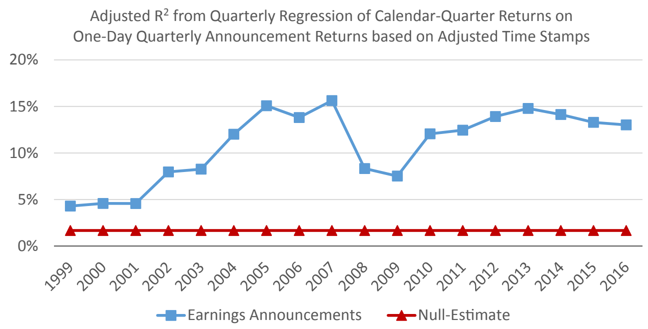

Fig. 2. The Adjusted R^2 values ("*ADJR*^{2}") from quarterly regressions of calendar-quarter returns on one-day quarterly announcement returns (adjusted for after-hours announcements) are plotted on the Y-axis. Firm-quarters with daily return data available for fewer than 60 trading days are excluded. The event sample includes 319,385 actual quarterly earnings announcements. The *Null -Estimate* for the Adjusted R^2 value is 1.67%, assuming every day in the quarter is equally like to explain variation in the quarterly return. Table 1 describes the adjustment for after-hours announcements using time stamps.

returns and three-day announcement returns. Interestingly, the adjusted R^2 measure declines slightly in 2013–2016, in contrast to the increase in *USTAT* over those years.[14]

5.1.2. Abnormal volume

Panel A of Fig. 3 shows the behavior of abnormal trading volume at earnings announcements in event time. Most notably, there is a significant day 0 impact after the adjustment of after-hours earnings announcements. Panel B of Fig. 3 shows the behavior of abnormal trading volume at earnings announcements by calendar year. The figure in Panel B displays evidence that earnings announcements convey more information than would be expected under the null in each of the years from 1999 through 2016. Furthermore, the intertemporal trend of *AVOL* is generally similar to that of *USTAT*, exhibiting a substantial increase beginning in 2002, a decrease in 2008 and 2009, and an increase in 2010 through 2016.

[14] We have no explanation for why the adjusted R^2 declines in 2013–2016 when the USTAT increases.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

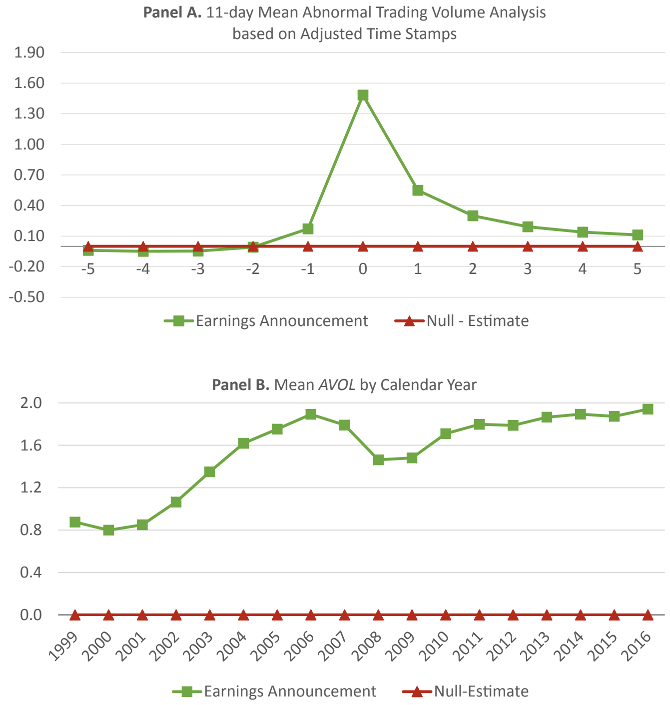

Fig. 3. The graph in Panel A plots the mean of abnormal trading volume over the 11-day window centered around earnings announcement days (adjusted for after-hours announcements). The earnings announcement sample includes 322,981 actual quarterly earnings announcements. The *Null-Estimate* sample is the mean of abnormal trading volume if earnings do not have information content. The graph in Panel B plots the mean information content of earnings announcements, the abnormal trading volume on earnings announcement dates adjusted for after-hours announcements ("*AVOL*"), by calendar year. The *Null-Estimate* is the expected value of *AVOL* if earnings announcements do not have information content. Table 1 describes the adjustment for after-hours announcements using time stamps.

5.2. Components of USTAT and AVOL

To provide insight into the factors contributing to the intertemporal change in the *USTAT* ratio, we decompose *USTAT* into its numerator, *USTAT_NM*, and denominator, *USTAT_DN*.[15] Table 2 and Fig. 4 Panel A present the mean of the numerator and the denominator by calendar year. The figure illustrates general co-movement between the numerator and denominator, with the most significant exception in years 2015–2016 as *USTAT_NM* ticks up more rapidly than *USTAT_DN*. The substantial increase in the *USTAT* ratio over 1999–2016 occurs with a number of different patterns in the components, including a decline in the numerator and denominator from 2000 to 2006, a relatively flat numerator along with decline in the denominator in 2010–2013 and a proportionately greater increase in the numerator than denominator in 2014–2016.

Table 2 and Fig. 4 Panel B present the mean of the numerator and the denominator of *AVOL* by calendar year. In contrast to the general decline we observe for *USTAT_DN*, we observe a decline in *AVOL_DN* from 1999 to 2002, a relatively flat pattern until it increases in 2013, followed by a decline in 2016. The numerator *AVOL_NM* exhibits a substantial increase after 2001, dips in 2008–2009 and then shows a more moderate increase for the rest of the sample period. Hence, the general increase in *AVOL* is not driven solely by a decline in *AVOL_DN*. For both *USTAT* and *AVOL*, the analysis of components underscores that we are conducting a relative comparison, and that the general increase over the sample period reflects changes in return variability and volume at earnings announcements that are proportionately greater than the changes in return variability and volume in non-announcement windows.

[15] We present the average of *USTAT_NM* and *USTAT_DN* for descriptive purposes, and note that the average of a ratio is not equal to the ratio of the averages.

Please cite this article as: Beaver, W.H et al., Increased market response to earnings announcements in the 21st century: An Empirical Investigation, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101244

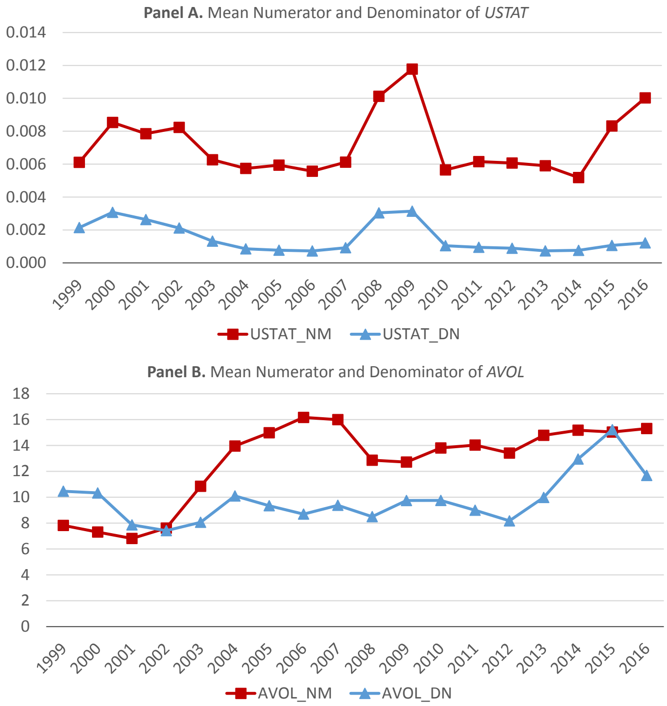

Fig. 4. The graph in Panel A plots the mean *USTAT_NM* and *USTAT_DN* of 323,060 quarterly earnings announcements. *USTAT_NM* is the squared residual return on the date of earnings announcement and the numerator of *USTAT. USTAT_DN* is the variance of residual returns during the non-announcement period and the denominator of *USTAT.* The graph in Panel A plots the mean *AVOL_NM* and *AVOL_DN* of 322,981 quarterly earnings announcements. *AVOL_NM* is the standardized shares-outstanding scaled trading volume on the date of earnings announcement and the numerator of *AVOL. AVOL_DN* is the standard deviation of shares-outstanding scaled volume in the non-announcement period and the denominator of *AVOL.*

5.3. Concurrent disclosure variables

In this section, we examine the ability of management guidance, analyst forecasts and disclosed financial statement items to explain the differences in *USTAT.* We present a series of figures that illustrate the differences over time. This form of presentation permits us to examine cross-sectional differences, holding time constant, and time series differences holding the cross-sectional variable constant. The subsequent section reports the findings of multivariate analysis that includes all of the disclosure variables along with additional control variables.

5.3.1. Management guidance

Consistent with findings by Anilowski et al. (2007) and Rogers and Van Buskirk (2013) for earlier sample periods, the percentage of earnings announcements with concurrent management forecasts increases from less than 3% in 1999 to 36% in 2016, as reported in Fig. 5 Panel A. Fig. 5 Panel B shows that the mean *USTAT* for earnings announcements with bundled management guidance is greater than the mean *USTAT* for earnings announcements without concurrent management guidance in each of the 18 years. These findings indicate that guidance either adds to the informativeness of earnings announcements, is issued selectively with more informative earnings announcements, or affects investors' inferences through some other mechanism. We note that the relative market response to stand-alone earnings announcements without guidance exhibits the same pattern of increases and decreases as earnings announcements with guidance. The increase in guidance over the sample period is thus not the sole factor contributing to the increase in *USTAT* at earnings announcements.

5.3.2. Analyst forecasts

The percentage of concurrent analyst forecasts increases over time from 34% in 1999 to 70% in 2016 as shown in Fig. 6 Panel A. Fig. 6 Panel B shows that the mean *USTAT* values for earnings announcements bundled with analyst forecasts are greater than those for stand-alone earnings announcements in each of the 18 years. However, similar to our findings for guidance, the mean *USTAT* of stand-alone earnings announcements also exhibits an increasing pattern, indicating the increased frequency of analyst forecasts is not the sole explanation for this pattern.

5.3.3. Financial statement line items

Fig. 7 Panel A displays the percentage of financial statement items disclosed in earnings announcements over time. The percentage of total financial statement items ("*FS*") increases from 22% in 1999 to 57% in 2016. The percentages of income statement items ("*IS*"), balance sheet items ("*BS*"), and cash flow statement items ("*SCF*") increase from 58%, 26%, and 0.5% in

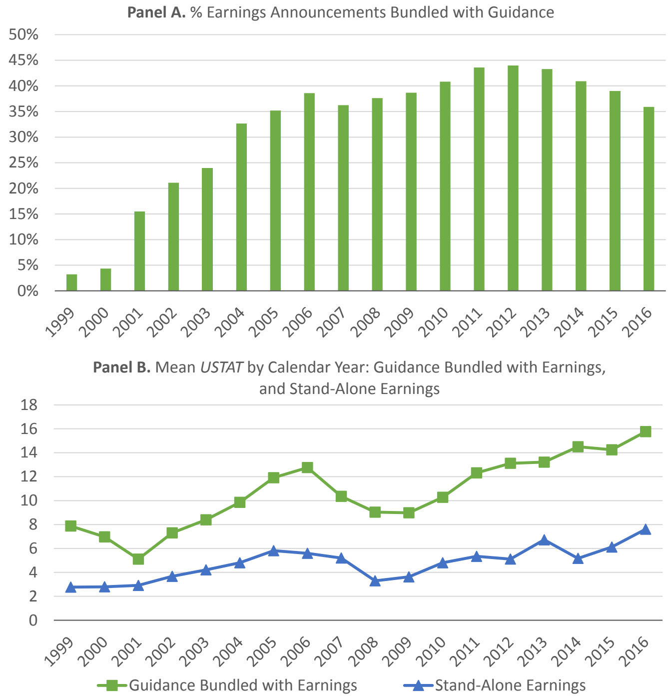

Fig. 5. The graph in Panel A plots the % of earnings announcements that are bundled with management guidance. The graph in Panel B plots the mean information content of two portfolios: the Guidance Bundled with Earnings portfolio includes management guidance issued on the same day as earnings announcements; the Stand-Alone Earnings portfolio includes earnings announcements without concurrent management guidance or analyst forecasts. The underlying numbers are reported in Table 7 Panel A.

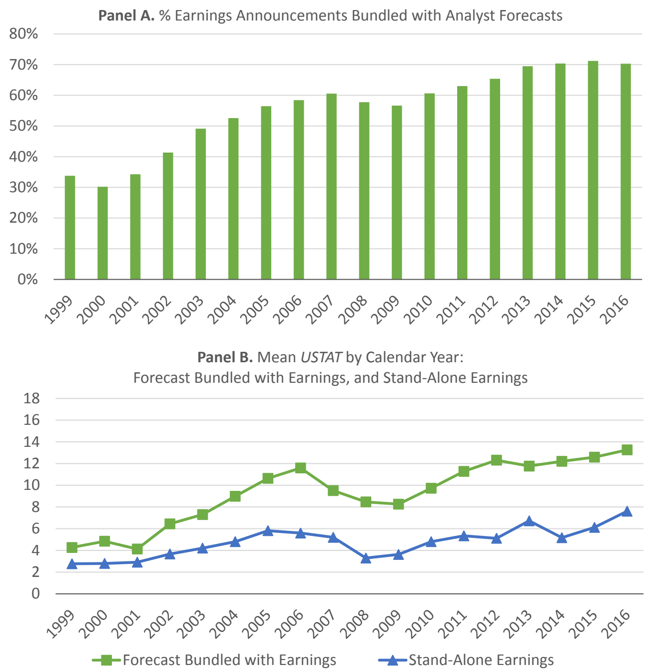

Fig. 6. The graph in Panel A plots the % of earnings announcements that are bundled with analyst forecasts. The graph in Panel B plots the mean information content of two portfolios: the Forecasts Bundled with Earnings portfolio includes all analyst forecasts issued concurrent with earnings; the Stand-Alone Earnings portfolio includes earnings announcements without concurrent management guidance or analyst forecasts. The underlying numbers are reported in Table 7 Panel B.

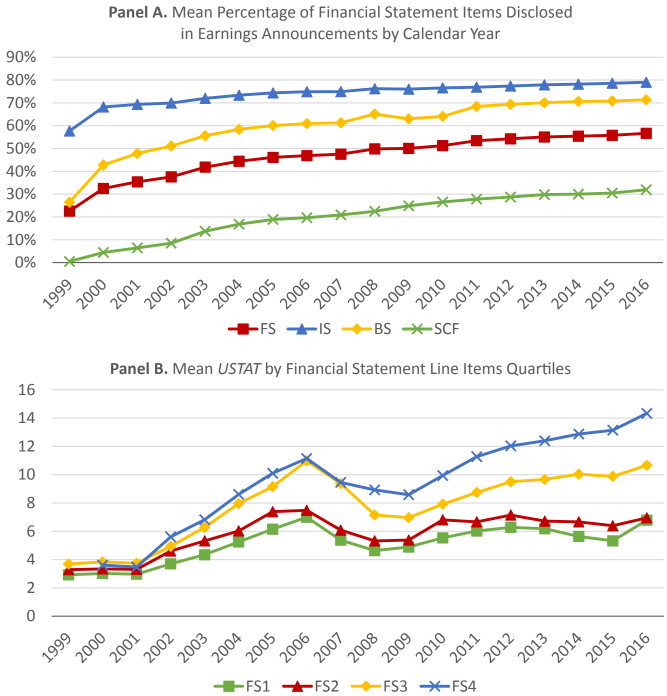

Fig. 7. The graph in Panel A plots the percentage of Financial Statement Line Items (FS), Income Statement line items (IS), Balance Sheet line items (BS), and Statement of Cash Flow line items (SCF) released in 248,412 earnings announcements with available data from Compustat Snapshot. The graph in Panel B plots the mean information content of earnings announcements, ***USTAT,*** by FS Quartiles. For the pooled sample, we assign firm-quarters with the lowest percentage of Financial Statement line items to quartile 1 (FS1) and firm-quarters with the highest percentage of Financial Statement line items to quartile 4 (FS4). No observation is assigned to FS4 in 1999. Appendix 2 provides details on the Financial Statement line items included.

1999 to 79%, 71%, and 32% in 2016, respectively. The data indicate firms are disclosing more financial statement line items in earnings announcements over time.

Fig. 7 Panel B presents a description of mean *USTAT* values by *FS* quartiles and calendar year. For the pooled sample, we assign firm-quarters with the lowest *FS* to quartile 1 and firm-quarters with the highest *FS* to quartile 4. The figures show that firm-quarters with greater *FS* have greater mean *USTAT* values than firm-quarters with lower *FS* in each of the 18 years. The findings indicate greater disclosure of financial statement items is a factor in the increase in market response to earnings over time. However, given the lowest quartile exhibits a similar though less pronounced pattern of increase and decline, the findings suggest these disclosures are at most a partial explanation for the increase in *USTAT.* Furthermore, the percentage of financial statement items is only slightly increasing between 2006 and 2011, whereas the *USTAT* shows a significant decline and then increase in these years.

5.4. Multivariate regression results

We next assess the incremental association of these variables to each other and to control variables using multivariate analysis. Table 3 reports the descriptive statistics on variables included in the multivariate model, and Pearson and Spearman correlations for the variables in the regressions. The descriptive statistics in Panel A document that the mean 1-day *USTAT* is 7.73, and the median is 1.77; both the mean and median are greater than the hypothetical null value of 1 and the 99th percentile of the null distribution, 1.56. Concurrent management guidance and analyst forecasts are released in 41% and 70% of the firm-quarters, respectively, and 47% of financial statement line items are disclosed.

The correlations in Panel B reveal several interesting patterns. The Pearson correlation between *USTAT* and *AVOL* is 0.649, indicating significant association between our primary measures of market response. The association between *USTAT* and $ADJR^2$ is significantly positive but weaker, reflecting the fact that $ADJR^2$ is measured at the quarterly level.[16] The Pearson correlation of 0.666 between *USTAT* and *USTAT_NM* is substantially greater in magnitude than the −0.117 correlation with *USTAT_DN*. This pattern is even more striking for *AVOL*, where the correlation with *AVOL_NM* is *0.737* and the correlation with *AVOL_DN* is −0.018. *USTAT* is positively associated with *T* (0.164), *GUIDANCE* (0.167), *AF* (0.154), *FS* (0.158), *IS* (0.118), *BS* (0.124), and *SCF* (0.136). In addition, *GUIDANCE* is positively associated with *AF* (0.273) and with *FS* (0.286), which indicates that

[16] The Pearson correlation between the mean quarterly *USTAT* and $ADJR^2$ is 0.703.

The sample comprises 203,127 firm-quarters in the COMPUSTAT North America database with time stamps from Bloomberg, IBES, or RavenPack and variables available for our multivariate regression analysis. See Table 1 for sample summary. Panel A presents distributional statistics for the primary variables in our analyses. Panel B presents the Pearson and Spearman correlations among these variables.

concurrent management guidance is more likely to be associated with concurrent analyst forecasts and greater reporting of disaggregated financial statement line items.

Table 4 presents the main results for the multivariate *USTAT* regressions, and shows that the relationships reported for the bivariate analyses are preserved. For each of the models, the coefficients on control variables are as expected: the coefficients on *NUMESTQ*, *NONDEC31* and *ABSFE_ST* are significantly positive and the coefficients on *LOSS* and *FIN* are significantly negative, consistent with Beaver, McNichols and Wang (2018a).

The estimation results for Model 1 confirm a significant positive association between *T* and *USTAT* (coefficient 0.480, t-stat 12.96), consistent with the general trend in the figures. After including the control variables in Model 2, the positive association between *T* and *USTAT* remains significant (coefficient 0.484, t-stat 14.87).

When *GUIDANCE* is included in Model 3, we see a significant positive relation between *USTAT* and *GUIDANCE* (coefficient 2.783, t-stat 9.68). Consistent with the bivariate relationship presented in Fig. 5, the market response to earnings announcements for Guidance firms is significantly greater than for No-Guidance firms. Furthermore, the coefficient on *T* declines from 0.484 to 0.409, indicating guidance partially explains the increasing time trend in *USTAT*. This may occur because guidance adds to the information investors learn at earnings announcements, or because guidance tends to occur when there is more information in the earnings press release.

When *AF* is included in Model 4, we see a significant positive relation between *USTAT* and *AF* (coefficient 2.866, t-stat 9.62). Consistent with the bivariate relationship presented in Fig. 6, the market response to earnings announcements for firm-quarters with concurrent analyst forecasts is significantly greater than for firm-quarters with no concurrent analyst forecasts. The coefficient on *T* decreases from 0.484 to 0.416 with the addition of *AF* to Model 2, our base for comparison.

The specifications in Models 5 and 6 examine the explanatory power of concurrently disclosed financial statement items. In Model 5, we see a positive association between *USTAT* and *FS* (coefficient 5.225, t-stat 9.69). In Model 6, we see positive associations between *USTAT* and % of financial statement items in each of three financial statements (*IS*: coefficient 2.469,

Table 4

The sample comprises all firms in the COMPUSTAT North America database with time stamps from Bloomberg, IBES, or RavenPack. The dependent variable is the one-day U-statistic (*USTAT*). *T* is a trend variable that takes on a value from 1 to 18 for calendar years 1999–2016. *GUIDANCE* is an indicator variable equal to 1 if management guidance is issued on the day earnings are announced and 0 otherwise. *AF* is an indicator variable that is equal to 1 if any analyst issues her forecast on the day earnings are announced and 0 otherwise. *FS* is the percentage of financial statement items disclosed in the earnings announcement. *IS [BS] {SCF}* is the percentage of income statement [balance sheet] {cash flow statement} items disclosed in the earnings announcement. Please refer to Appendix 2 for details on the line items included. *LCV* is the natural log of market capitalization. *NUMESTQ* is the number of analysts forecasting quarterly earnings at fiscal quarter end. *FIN* is an indicator variable that is equal to 1 if a firm has an SIC code between 6000 and 6999 and 0 otherwise. *LOSS* is an indicator variable that is equal to 1 if *PTEBS*, Pre-Tax Earnings Before Special Items, is negative and 0 otherwise. *LAG* is the number of days after the end of the fiscal quarter that earnings are announced. *NONDEC31* is an indicator variable equal to 1 for firm-quarters with Non-Dec31 fiscal year end and 0 otherwise. *ABSFE_ST* is the absolute value of the difference between IBES realized earnings and the fiscal-quarter-end median analyst forecast, scaled by price.. We winsorize variables at 1% and 99% and estimate ordinary least squares regressions. *** [**](*) refers to significance at the 1% [5%](10%) level. Following Gow et al. (2012), we cluster standard errors by firm and calendar year.

t-stat 3.35; *BS*: coefficient 2.056, t-stat 5.01; *SCF*: coefficient 1.607, t-stat 3.67). Consistent with the bivariate relationship presented in Fig. 7, the price response to earnings announcements is positively associated with the percentage of financial statement line items disclosed in earnings announcements. Furthermore, the inclusion of financial statement items in Models 5 and 6 coincides with a decrease in the coefficient on *T*, which reflects the time trend in *USTAT*. These findings indicate the increase in financial statement line item disclosure is associated with increased price response to earnings announcements. These findings are consistent with the findings of Francis, Schipper and Vincent (2002a) on the significance of detailed income statements and statements of cash flows and complement the findings in Francis and Schipper (1999), Collins et al. (2009), and Barth et al. (2018) on the increasing role of balance sheet information in explaining share price revisions.

When all the variables are included in Models 7 and 8, the relationships observed in Models 3–6 are preserved. In Model 7, having concurrent management guidance (analyst forecast) is associated with a 2.323 (2.422) increase in *USTAT*. A one-standard deviation (0.24) increase in *FS* is associated with a 1.02 (0.24*4.251) increase in *USTAT*. A firm-quarter observation with concurrent guidance and analyst forecasts, and financial statement line item disclosures one standard deviation above average would be predicted to have a *USTAT* that is greater by 5.765 than that of a firm with no concurrent guidance or forecast, and average financial statement line item disclosures. A 5.765 increase in *USTAT* reflects an increase in relative squared return variability comparable to what would be experienced on an additional 5.765 non-earnings days. These metrics suggest the effects we are documenting are economically as well as statistically significant.

The coefficient on *T* remains significantly positive (Model 7 coefficient 0.284, t-stat 10.55; Model 8 coefficient 0.282, t-stat 9.99), but is now 58% of the coefficient observed in Model 2 (0.484). The disclosure of management guidance, analyst forecasts and financial statement line items explains 42% of the increase in *USTAT* over our sample period. This may reflect the

The sample comprises all firms in the COMPUSTAT North America database with time stamps from Bloomberg, IBES, or RavenPack. The dependent variable is 1000 times the numerator of the one-day U-statistic *USTAT_NM*. *USTAT_DN* is the denominator of *USTAT*. *T* is a trend variable that takes on a value from 1 to 18 for calendar years 1999−2016. *GUIDANCE* is an indicator variable equal to 1 if management guidance is issued on the day earnings are announced and 0 otherwise. *AF* is an indicator variable that is equal to 1 if any analyst issues her forecast on the day earnings are announced and 0 otherwise. *FS* is the percentage of financial statement items disclosed in the earnings announcement. *IS [BS] {SCF}* is the percentage of income statement [balance sheet] {cash flow statement} items disclosed in the earnings announcement. Please refer to Appendix 2 for details on the line items included. *LCV* is the natural log of market capitalization. *NUMESTQ* is the number of analysts forecasting quarterly earnings at fiscal quarter end. *FIN* is an indicator variable that is equal to 1 if a firm has an SIC code between 6000 and 6999 and 0 otherwise. *LOSS* is an indicator variable that is equal to 1 if *PTEBS*, Pre-Tax Earnings Before Special Items, is negative and 0 otherwise. *LAG* is the number of days after the end of the fiscal quarter that earnings are announced. *NONDEC31* is an indicator variable equal to 1 for firm-quarters with Non-Dec31 fiscal year end and 0 otherwise. *ABSFE_ST* is the absolute value of the difference between IBES realized earnings and the fiscal-quarter-end median analyst forecast, scaled by price. We winsorize variables at 1% and 99% and estimate ordinary least squares regressions. *** [**](*) refers to significance at the 1% [5%](10%) level. Following Gow et al. (2012), we cluster standard errors by firm and calendar year.

additional information these disclosures provide directly, or investors' inferences about what these disclosures imply for managers' and analysts' underlying information.

Table 5 presents estimation results for the above models where the dependent variable is the numerator of *USTAT*, *USTAT_NM*. These specifications include *USTAT_DN* as an explanatory variable, and therefore allow the relation between the numerator and denominator to include an intercept and to have a coefficient different from one. This allows us to control directly for the effect of the denominator of *USTAT* in our analysis, and to examine whether the pattern we document for *USTAT* remains after controlling for variation in the magnitude of the denominator.

For the specification in Model 1, there is a significant positive association between *T* and *USTAT_NM* (coefficient 0.164, t-stat 7.32), consistent with the findings in Table 4 for *USTAT*. The coefficient on *USTAT_DN* is 2.14, and highly significant (t-stat 17.32). The findings indicate that without further controls, the announcement effect is on average double the magnitude of squared price revision in the non-announcement period. After including the control variables in Model 2, the positive association between *T* and *USTAT* remains significant (coefficient 0.178, t-stat 7.88).

The estimation results in Models 3,4 and 5 show that as we include *GUIDANCE*, *AF* and *FS*, each has significant explanatory power for *USTAT_NM*. Furthermore, as each concurrent disclosure variable is included, the coefficient on *T* is reduced, indicating these variables have explanatory power for the time trend in the numerator of *USTAT*.

The specification in Model 6 examines the explanatory power of line items from each concurrently disclosed financial statement. Although the coefficients on *IS* and *BS* are positive and significant when all three *FS* components are included, the

The sample comprises all firms in the COMPUSTAT North America database with time stamps from Bloomberg, IBES, or RavenPack. The dependent variable is the one-day abnormal trading volume (*AVOL*). *AVOL_NM* and *AVOL_DN* are the numerator and denominator of *AVOL*. *T* is a trend variable that takes on a value from 1 to 18 for calendar years 1999–2016. *GUIDANCE* is an indicator variable equal to 1 if management guidance is issued on the day earnings are announced and 0 otherwise. *AF* is an indicator variable that is equal to 1 if any analyst issues her forecast on the day earnings are announced and 0 otherwise. *FS* is the percentage of financial statement items disclosed in the earnings announcement. *IS [BS] {SCF}* is the percentage of income statement [balance sheet] {cash flow statement} items disclosed in the earnings announcement. Please refer to Appendix 2 for details on the line items included. *LCV* is the natural log of market capitalization. *NUMESTQ* is the number of analysts forecasting quarterly earnings at fiscal quarter end. *FIN* is an indicator variable that is equal to 1 if a firm has an SIC code between 6000 and 6999 and 0 otherwise. *LOSS* is an indicator variable that is equal to 1 if *PTEBS*, Pre-Tax Earnings Before Special Items, is negative and 0 otherwise. *LAG* is the number of days after the end of the fiscal quarter that earnings are announced. *NONDEC31* is an indicator variable equal to 1 for firm-quarters with Non-Dec31 fiscal year end and 0 otherwise. *ABSFE_ST* is the absolute value of the difference between IBES realized earnings and the fiscal-quarter-end median analyst forecast, scaled by price. We winsorize variables at 1% and 99% and estimate ordinary least squares regressions. *** [**](*) refers to significance at the 1% [5%](10%) level. Following Gow et al. (2012), we cluster standard errors by firm and calendar year.

coefficient on *SCF* is no longer significant.[17] The results for Models 7 and 8 show the significance of concurrent disclosures remains when all concurrent disclosures are included in the model. Furthermore, the estimation results for Models 7 and 8 show that when all concurrent disclosures are included, the coefficient on *T* decreases to 0.04 ($t = 1.67$) and 0.034 ($t = 1.38$). These results indicate that our findings are robust to variation in the denominator of *USTAT*, and that the substantial decline in *USTAT_DN* does not affect our conclusions.

Table 6 presents the related specifications for *AVOL* and *AVOL_NM* as dependent variables. For brevity, we present models 1, 2, 7 and 8 as specified in Tables 4 and 5 for each dependent variable. The findings indicate that similar to the *USTAT* regressions, inclusion of concurrent disclosure variables substantially reduces the coefficient on T, from 0.068 in Model 2 to 0.026 in Model 4, thus explaining 62% of the time trend in abnormal volume at earnings announcements. In the *AVOL* specifications, each of the concurrent disclosure variables, including line items from each financial statement, have significant explanatory power. The findings for *AVOL_DN* are very similar to those of *USTAT_DN* in Table 5. For the *AVOL_NM* specifications, the coefficient on the time trend decreases from 0.479 in Model 6 to 0.121 in Model 8 which includes our concurrent

[17] Untabulated findings document that the coefficients on *IS*, *BS* and *SCF* are positive and significant when entered individually into models 6 and 8.

Panel A presents the mean one-day U-statistic (*USTAT*) of three portfolios: Guidance Bundled with Earnings, Stand-Alone Guidance, and Stand-Alone Earnings. The Guidance Bundled with Earnings portfolio includes management guidance issued on the same days earnings are announced. The Stand-Alone Guidance portfolio includes management guidance issued on days earnings are not announced. The Stand-Alone Earnings portfolio includes earnings announcements without either concurrent management guidance or concurrent analyst forecasts. The seventh column reports the ratio of the number of management guidance bundled with earnings announcements to the number of earnings announcements. The eighth column reports the ratio of the number of Stand-Alone Guidance to the number of management guidance. The ninth column reports the ratio of the number of Stand-Alone Earnings to the number of earnings announcements.

Panel B presents the mean one-day U-statistic (*USTAT*) of three portfolios: Forecasts Bundled with Earnings, Stand-Alone Analyst Forecast, and Stand-Alone Earnings. The Forecast Bundled with Earnings portfolio includes analyst forecasts issued on earnings announcement days. The Stand-Alone Analyst Forecast portfolio includes analyst forecasts issued on days when earnings are not announced. The Stand-Alone Earnings portfolio includes all earnings announcements without concurrent management guidance and concurrent analyst forecasts. The seventh column reports the ratio of the number of analyst forecasts bundled with earnings announcements to the number of earnings announcements. The eighth column reports the ratio of the number of Stand-Alone Analyst Forecast to the number of analyst forecasts. The ninth column reports the ratio of the number of Stand-Alone Earnings to the number of earnings announcements.

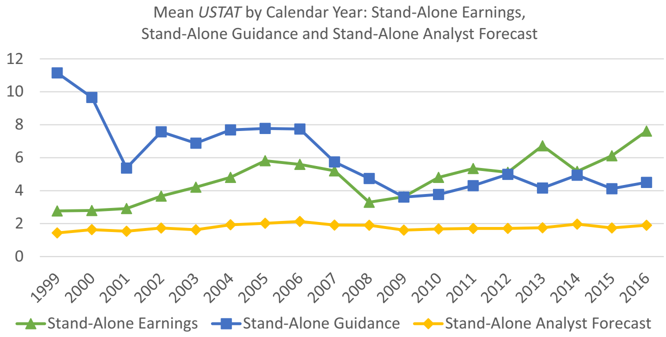

Fig. 8. This graph plots the mean information content of three portfolios: the Stand-Alone Earnings portfolio includes earnings announcements without concurrent management guidance or analyst forecasts; the Stand-Alone Guidance portfolio includes management guidance issued on days earnings are not announced; the Stand-Alone Analyst Forecast portfolio includes analyst forecasts issued on days when earnings are not announced. The underlying numbers are reported in Table 7 Panel A, B.

Table 8
The information content of earnings announcements, management guidance and analyst forecasts.

Regression of one-day information content on time trend interacted with indicator variables for stand-alone earnings, stand-alone guidance and stand-alone forecasts

Variable	*T*SE*	*T*SA*	*T*SG*	*SE*	*SA*	*SG*	*LCV*	ADJR^2	NOBS
Coefficient	0.204***	0.025***	−0.279***	5.512***	4.899***	11.839***	−0.232***	1.20%	2,156,710
t-stat	7.15	3.85	−4.02	13.38	14.18	12.94	−12.00		

Coefficient Comparison	F-stat	p-value
*T*SE = T*SA*	40.86	<0.001
*T*SE = T*SG*	48.12	<0.001

The sample comprises stand-alone earnings announcements, stand-alone guidance and stand-alone analyst forecasts. The dependent variable is the one-day U-statistic (*USTAT*). *T* is a trend variable that takes on a value from 1 to 18 for calendar years 1999–2016. *SE* is an indicator variable equal to 1 for all earnings announcements without concurrent management guidance and concurrent analyst forecasts and 0 otherwise. *SA* is an indicator variable equal to 1 for all analyst forecasts issued on days when earnings are not announced and 0 otherwise. *SG* is an indicator variable equal to 1 for all management guidance issued on days earnings are not announced and 0 otherwise. *LCV* is the natural log of market capitalization. *** [**](*) refers to significance at the 1% [5%](10%) level. Following Gow et al. (2012), we cluster standard errors by firm and calendar year.

disclosure variables, indicating concurrent guidance, analyst forecasts and financial statement line item disclosures explain approximately 75% of the time trend in this specification.

5.5. The market response to earnings releases, management guidance and analyst forecasts

Our final tests compare the market response to earnings announcements to the response to management guidance and analyst forecasts issued separately from earnings. Fig. 8 shows the mean *USTAT* for three portfolios: Stand-Alone Earnings, Stand-Alone Guidance and Stand-alone Analyst Forecasts.[18] Over our sample period from 1999 to 2016, we observe a substantially increased response to Stand-Alone Earnings, a decreased response to Stand-Alone Guidance, and a slightly increased response to Stand-Alone Analyst Forecasts.

Table 7 Panel A shows there has been a substantial decrease in the frequency of Stand-Alone Earnings and Stand-Alone Guidance over time, and an increase in the frequency of Guidance Bundled with Earnings. This is consistent with firms increasingly choosing to issue management guidance with earnings announcements rather than at other times. Surprisingly, the mean *USTAT* for Stand-Alone Guidance firm-years decreases over time, from 11.15 in 1999 to 4.50 in 2016. In contrast, the mean *USTAT* for Stand-Alone Earnings firm-years increases over time, from 2.77 in 1999 to 7.61 in 2016.

Table 7 Panel B shows an increase in the frequency of Forecasts Bundled with Earnings, along with a small decline in the frequency of Stand-Alone Forecasts and the more substantial decline in the frequency of Stand-Alone Earnings Announcements noted above. The total number of analyst forecast days is 2,123,832, more than six times the 323,060 earnings announcements. This greater frequency reflects the fact that multiple analysts can cover a single firm and analysts can update their beliefs between earnings announcements. The findings indicate the mean *USTAT* for Stand-Alone Forecasts increases from 1.43 to 1.90, a substantially smaller increase than that observed for the Stand-Alone Earnings sample.

[18] For these analyses, the Stand-Alone Earnings portfolio has neither management guidance nor analyst forecasts, so we exclude earnings issued with analyst forecasts (guidance) in the comparison to Stand-Alone Guidance (Stand-Alone Forecasts). For this reason, the sum of columns 1 and 5 do not total 100% of the available observations in the denominator in column 7.

The visual and numeric evidence suggests very different time trends for *USTAT* for Stand-Alone Earnings relative to that for Stand-Alone Guidance and Stand-Alone Analyst Forecasts. To assess the statistical significance of this pattern, we regress *USTAT* on indicators for Stand-Alone Earnings, Stand-Alone Guidance[19] and Stand-Alone Forecasts, and each of these indicators interacted with T. The findings are reported in Table 8, and document that the over-time trend in market response to guidance and analyst forecasts is significantly different from the over-time trend for earnings (with F-statistics of 48.12 and 40.86, respectively). These findings indicate that the increased market response to earnings announcements does not reflect a change in investor response to information events in general.

5.6. Robustness tests

We have conducted a number of tests to assess the sensitivity of our findings to alternative research design choices, which we describe in the Internet Appendix. The analyses examine whether our results are sensitive to changes in the composition of our sample over time, to industry composition, to concurrent dividends, to analyst coverage, and to two alternate measures of investor response, a 3-day *USTAT* and the Ball and Shivakumar (2008) adjusted R^2 measure. The findings establish that our conclusions are robust to these alternatives. Most notably, we document that our findings hold for firms without analyst coverage, implying analysts' information acquisition and disclosure activities cannot fully explain the increase in information content of earnings announcements over our sample period. Our findings are similar for the 3-day *USTAT* though the magnitudes of the observed effects are substantially smaller than those for the 1-day *USTAT*. We find that the adjusted R^2 measure exhibits a significant time trend, similar to *USTAT*. Finally, we note that our concurrent information variables fully explain the time trend in this measure.

6. Conclusions

This paper examines the role of concurrent management guidance, analyst forecasts and financial statement line item disclosures in the striking increase in market response to earnings announcements in the 21st century. The findings, based on the return measure *USTAT* and abnormal volume measure *AVOL*, provide a number of new insights. First, we find that guidance, analyst forecasts and disaggregated line items are more frequently bundled with earnings announcements, and that each of these concurrent disclosures are associated with the increase in information content of earnings announcements over time. Furthermore, the extent of line item disclosure from the income statement and balance sheet has explanatory power for price and volume response at earnings dates. This explanatory power is incremental to concurrent guidance by management and forecasts by analysts, highlighting the significance of financial statement information, and especially information about earnings.

We decompose our measure of price variability and volume at earnings dates to separately examine the numerator and denominator. We document that relative price variability at non-announcement dates (the denominator of the *USTAT* ratio) has declined significantly over our sample period. This finding likely reflects broader economic trends that have reduced return volatility, and may also reflect shifts in disclosure such as increased bundling of guidance with earnings announcements. Our tests with the numerator of the earnings date return response, *USTAT_NM*, rather than *USTAT*, document a similar significant time trend and similar associations with concurrent disclosure. This supports our interpretation that concurrent disclosures are a substantial factor in the increase in *USTAT* over time. We find that the denominator of *AVOL* does not exhibit a secular decline, indicating the increase in abnormal volume is not due to denominator effects.

In addition, we examine the magnitude of price response to management guidance and analyst forecasts issued separately from earnings announcements. We find that the average *USTAT* for stand-alone earnings announcements over the full sample period is similar to the *USTAT* for stand-alone management guidance announcements. However, surprisingly, different trends have emerged over our sample period: the *USTAT* on management guidance dates declines over the sample period, whereas the *USTAT* at stand-alone earnings announcements generally increases. These findings support the conclusion that greater relative return variability at earnings announcements reflects the increase in information released at this time rather than more general changes in how investors respond to earnings-related information.

Taken as a whole, the findings shed light on why earnings announcements are an increasingly important information source for investors in the 21st century. Because we assess the market response to guidance, analyst forecasts and financial statement line items incremental to each other and an extensive set of control variables, we believe the inference of a causal relation between disclosure of these information items and investor response is warranted. However, this interpretation is subject to the caveat that if disclosures or actions that are omitted from our research design correlate with the disclosures included in our study, our inferences could be affected.

The findings generate some intriguing patterns and questions for future research. First and foremost, while our concurrent information variables explain a significant part of the increase in market response over time, our quest for an explanation is not complete. The extent to which refinements of our concurrent information measures or additional variables fully explain the increase awaits future research. Despite this, the magnitude of the increase we document and the role of concurrent information related to earnings in explaining this are important findings, particularly in light of the findings of decreased

[19] Our main results include both earnings and non-earnings guidance. Untabulated findings document that the over-time trend in market response to stand-alone earnings guidance is declining and significantly different from the over-time trend for stand-alone earnings announcements.

value relevance of earnings in other studies. Second, while we find that different measures of investor response to earnings each show an increase after 2001, their patterns over time show differences that merit exploration. Third, whether the increase in concurrent information at earnings announcements and in market response continues past the time of our study is an open question. Lastly, the influence of the regulatory environment on the information content of earnings announcements and management guidance merits further exploration. These directions can further our understanding of the forces that influence the quality of information managers provide to investors through earnings announcements, financial reports, and voluntary disclosures.

Acknowledgement

The authors thank Michelle Hanlon (editor) and Edward Maydew (the referee) for their many helpful comments on the paper. We also thank Andy Bauer, Jennifer Francis, Katherine Schipper, Pat O'Brien, Andy Van Buskirk, Christine Wiedman, and Paul Zarowin (discussant) for helpful discussions and Paul Reist and Nora Richardson for their assistance in data collection. The authors appreciate the many helpful comments from workshop and doctoral seminar participants at Stanford University, University of Illinois at Urbana-Champaign, University of Illinois at Chicago and University of Waterloo. Prior versions of the paper were circulated under the title: "Increased Information Content of Earnings Announcements in the 21st Century: An Empirical Investigation." Corporate Financial Disclosure Measurement in the Empirical Accounting Literature: A Review Article

OMAIMA A. G. HASSAN* and
CLAIRE MARSTON

ABSTRACT

This paper develops a framework for corporate financial disclosure measurement to identify and evaluate measures of financial disclosure employed in prior empirical accounting studies. It identifies two approaches: (i) a disclosure-based approach that investigates actual disclosure, operationalizes the concept of disclosure in terms of its main dimensions such as the quantity and quality of disclosure, and develops methods to measure them such as the disclosure index and textual analysis, and (ii) a non-disclosure-based approach that uses the values of some observable variables to proxy for disclosure such as market-based disclosure measures. The study also discusses the extent to which the reliability and validity of these different measures of disclosure are tested. The purposes of this review are: (i) to help future researchers identify exemplars and select or develop their own suitable disclosure measures, and (ii) to identify measurement issues relating to corporate financial disclosure and provide avenues for future research.

Keywords: accounting information; financial disclosure; financial reporting; measurement; reliability; validity.

1. INTRODUCTION

Corporate financial disclosure[1] is any deliberate release of financial information, whether numerical or qualitative, required or voluntary, via formal or informal channels (Gibbins, Richardson, & Waterhouse, 1990, p. 122). Companies disclose information[2] through various means such as annual reports, conference calls, interim reports, prospectuses, press releases, and websites. Prior empirical accounting studies have attempted to develop various measures for financial disclosure, but to date there is no comprehensive systematic review that identifies and evaluates these measures. This paper addresses this gap and develops a framework for financial disclosure measurement based on a review of 280 prior empirical studies published in top rated accounting journals.

Financial disclosure is important because it is the primary means of communication between management and outside investors as well as market participants in general. Hence the literature on financial disclosure is enormous and investigates a wide range of issues such as the determinants of voluntary disclosure, the impact of regulatory change on the extent of disclosure, and the economic consequences of disclosure. Although many studies investigate financial disclosure for the private sector companies, others look at the public sector and not-for-profit organizations. In all these studies, disclosure plays a key role and must be measured in some way. However, measuring disclosure is difficult because disclosure is a theoretical construct which is not directly observable.

---

[1] Some researchers refer to the numbers in the financial statements as "financial reporting". Other scholars view numbers outside the financial statements and texts as "disclosure". Others view both these types as financial disclosure (e.g., Gibbins et al., 1990). We belong to the third school and adopt Gibbins et al.'s (1990) definition of corporate financial disclosure, which covers both the numbers in the financial statements and other numbers as well as texts in the disclosure vehicle.

[2] Corporate disclosure can also be directed to parties other than outside investors, such as stakeholders more generally, strategic investors, and strategic debtholders.

Previous review articles discuss several ways of measuring disclosure, by looking at either one method or one type of disclosure. For example, Marston and Shrives (1991) concentrate on the disclosure index, whereas Jones and Shoemaker (1994) examine textual analysis techniques. Healy and Palepu (2001) discuss concerns about measuring voluntary disclosure and consider the disadvantages of three measurement proxies: management forecasts, analyst ratings, and self-constructed disclosure indices developed by researchers. They consider that analyst ratings and self-constructed disclosure indices are likely to be noisy[3] measures of disclosure.

Beattie, McInnes, and Fearnley (2004) present a selection of methods for measuring narratives in annual reports, including methods reviewed by Jones and Shoemaker (1994) as well as Healy and Palepu (2001). Beyer, Cohen, Lys, and Walther (2010) expand on this list and include properties of reported earnings. Leuz and Wysocki (2016) enlarge this list and include binary indicators and frequency of disclosure. Table 1 provides an overview of the measures of disclosure identified in these studies; however, our study provides a more comprehensive review and discussion of various methods for measuring disclosure, and further extends the list to include measurements of disclosure through other observable variables such as market-based measures and the voluntary adoption of generally accepted accounting principles (GAAP). It goes further by developing a framework for corporate financial disclosure measurement and discussing some related measurement issues. The purpose of this framework is to provide a consistent approach for systematically collecting, analyzing, and evaluating existent measures of financial disclosure. We hope this will help

[3] Healy and Palepu (2001) consider that using these measures of disclosure as independent variables in prior studies are likely to suffer from omitted variable bias.

researchers to make more informed decisions about their choices of measures of financial disclosure or allow them to locate any new measure or method that they develop.

<<Insert Table 1 about here>>

Current gaps in the disclosure literature provide several motivations for our study. Firstly, a framework for disclosure measurement does not currently exist in the literature. Accounting studies do not specifically consider issues involved in measuring disclosure as a latent (unobservable) variable. Secondly, although this literature offers a variety of potential measures for disclosure, to date, there is no comprehensive systematic review that identifies and evaluates existent measures of disclosure. Thirdly, although the assessment of measures of disclosure is discussed to some extent in the extant accounting literature, a comprehensive analysis is lacking. Our study contributes to the literature by filling in these gaps through (i) developing a framework for corporate financial disclosure measurement, (ii) identifying and evaluating common measures of financial disclosure employed in prior empirical studies through a review of the literature from 2005 to 2016, and (iii) providing an in-depth discussion of some related empirical challenges including casual claims, and how the reliability and validity of different measures of disclosure are assessed. The purpose of this review is to help future researchers to identify exemplars and to guide them in the selection or development of their own suitable measures. Additionally, our study highlights some measurement issues related to corporate financial disclosure and provides avenues for future research.

A review of the empirical accounting literature was conducted to identify measures of financial disclosure employed in articles published between 2005 and 2016; articles in accountancy journals that are rated 3* or 4* by the Association of Business Schools were investigated.[4] We believe that selecting articles from top rated accounting journals over a 12-year period provides a reasonably up-to-date time frame for this review. Employing a Boolean search for 'financial reporting' or 'financial disclosure', on the title, abstract and keywords fields of the selected journals over the selected time frame, the results show 2514 articles published between 2005 and 2016. The titles, abstracts and conclusions were then carefully read to identify empirical studies of corporate financial disclosure/reporting in the private sector. We excluded[5] the following studies: intellectual capital studies, timely disclosure studies, research that empirically examines the economic consequences of individual items of financial disclosure, and image/picture disclosure studies. The application of these research criteria yielded a sample of 280 disclosure studies. Table 2 presents a break-down of these studies by journal and shows that most of them are published in the Accounting Review, Journal of Accounting and Economics, Journal of Accounting Research, and the International Journal of Accounting.

<<Insert Table 2 about here>>

We followed an inductive reasoning approach to develop a framework for disclosure measurement. From specific observations about measurements of disclosure developed in the empirical accounting literature, the analysis moves onto broader generalizations. To inform our analysis, we also consulted the literature on the problem associated with measurement of latent variables (Jarvis, MacKenzie, & Podsakoff, 2003; Goertz, 2008). We

[4] This choice may seem biased toward US academic journals. The Association of Business Schools rankings are heavily used in the UK during the selection of academic staff and articles to be entered in the periodic Research Excellence Framework exercise by which UK University departments are ranked. US–based, highly quantitative journals are predominant in these rankings. However, in the first version of this paper prior to our systematic review, we did not apply any restrictions to the academic papers covered, and we reached similar conclusions about common financial disclosure measures in the accounting literature.

[5] We were pragmatically trying to make the review manageable by missing some disclosure areas out.

identified, evaluated and coded the different types of disclosure measures contained within the 280 studies and categorized them into 11 common measures of disclosure. These measures of disclosure are then classified into disclosure-based and non-disclosure-based measures.

The remainder of this paper is organized as follows: in Section 2 we develop a framework for disclosure measurement and identify as well as evaluate different measures of disclosure. In Section 3 we discuss causal claims in prior disclosure studies and explore the extent to which reliability and validity of measures of disclosure are tested within papers identified in the systematic review of the literature. Finally, in section 4 we discuss some measurement issues relating to financial disclosure and highlight areas for future research.

2. A FRAMEWORK FOR DISCLOSURE MEASUREMENT

In this section, we develop a framework to classify various measures of disclosure. To do this, either a deductive or an inductive reasoning approach can be followed.

A deductive reasoning approach works from the more general to the more specific, informally called a "top-down" approach. Applying the deductive approach when constructing or evaluating concepts and quantitative measures, Goertz (2008) suggests, among other things, that the first consideration must be the theory embodied in the concept. Another consideration should be the necessary (minimum) and sufficient (maximum) parts of the concept. However, there is no single theory of disclosure (Verrecchia, 2001), which makes it more complex to develop or evaluate a measure of disclosure. Additionally, empirical studies consider different types of disclosure, for example mandatory and voluntary disclosures. Also, financial disclosure can take different formats such as textual or numerical disclosure (e.g., Kravet & Muslu, 2013; Nelson & Rupar, 2015). This deductive approach is even more complex when we consider that within a single type of disclosure there are different dimensions that can be captured such as the quality and quantity of information disclosure (e.g., Wynn, 2008; Ernstberger & Grüning, 2013; André, Filip, & Moldovan, 2016). For all these reasons, it is probably impossible to adopt a deductive approach to disclosure measurement.

Alternatively, an inductive reasoning approach can be employed to develop a framework for disclosure measurement. Inductive reasoning is a type of thinking that involves identifying patterns in a data set to reach conclusions and build theories (Hair, Wolfinbarger, Money, & Samouel, 2011, p. 276). It moves from specific observations to broader generalizations and theories, informally called a "bottom-up" approach. Using this approach, we review 280 empirical accounting studies published in top rated accounting journals from 2005 to 2016 and identify[6] common proxies employed for financial disclosure. Table 3 shows a list of the common measures of disclosure identified in the review of the literature and provides some exemplars for each measure. It shows 11 different measures of financial disclosure with the classification approach being the most popular, while the disclosure survey (analyst ratings) and the voluntary adoption of quality GAAP are the least popular method employed in the recent empirical accounting literature.

---

[6] Since human coding is inevitably subjective, to ensure the reliability of our coding, the authors of the papers have agreed on the coding instructions of the different measures of disclosure before the coding took place. When in doubt, the same paper would be coded by both authors and any discrepancies were discussed and resolved. In addition, after the coding was finalized, a random sample of 40 papers has been re-coded (test-retest) by one of the authors. The recoding of measures of corporate financial disclosure was almost identical to the original ones, which indicates the reliability of our coding.

<<Insert Table 3 about here>>

Analyzing these common measures of disclosure, we identify two main measurement methods: a disclosure-based approach and a non-disclosure-based approach. A further classification[7] relates to whether the non-disclosure-based measure is a formative or reflective variable.

2.1 Disclosure-based approach

This approach investigates actual disclosure and reduces (operationalizes) it to its main dimensions such as quantity, quality, timing, complexity, tone and prominence. It attempts to measure one or more of these dimensions via various means such as textual analysis or the disclosure index approach. Table 4 provides a summary of common disclosure-based measures identified in this review of the literature.

<<Insert Table 4 about here>>

2.1.1 Classification approach

This approach involves sorting observations into mutually exclusive groups according to an aspect of corporate financial disclosure that is being studied. The focus could be broad such as a disclosure policy or a reporting regime, for example whether a firm publicly provide an annual report or files a 10-K report, or narrow such as specific disclosure, for example whether a firm hosts conference calls or provides management forecasts (Leuz & Wysocki,

[7] We acknowledge that some overlap inevitably exists between the sub-clusters. For example, textual analysis methods can be employed to create textual sentiments, but to recognize that sentiment analysis is not limited to written words only and that it can be employed on quantitative data, we prefer to address it as a separate sub-cluster, even if it has some overlap with textual analysis.

2016). Then, it uses a categorical variable to represent these groups in numerical terms. The resultant measure of corporate financial disclosure could be dichotomous or multicategory. For example, Cannizzaro and Weiner (2015) classify disclosures into minimal, partial, and full disclosure to assess transparency. Marquardt and Wiedman (2007) measure the quality of disclosure by classifying information on contingently convertible securities to "high-quality" if the number of shares related to the convertible securities is disclosed; "medium-quality" if enough information is provided for investors to calculate the dilutive impact; and "low-quality" if insufficient information is provided. Gillan and Panasian (2014) sort firms into cross-listed (foreign) firms filing a 40-F, 20-F, 10-K form, or their US-matched domestic counterparts to capture the differential disclosure complexity in these filings. Hollander et al. (2010) assess incomplete disclosure by determining whether requests for information made during conference calls are granted. If at least one request is not granted, they mark this call as containing incomplete disclosure. Bowen et al. (2005), Files, Swanson, and Tse (2009), and Marques (2010) assess the prominence of disclosure using a classification approach based on the position of information in the disclosure vehicle.

A classification approach is commonly applied to specific disclosures such as conference calls, segment information, management forecasts, disclosure of non-GAAP numbers, material restatement and material weakness disclosures, and financial statement disclosure (e.g., Kimbrough, 2005; Botosan & Stanford, 2005; Marques, 2006; Nagy, 2010; Weiss, 2014; Bernard, 2016). However, given the simplicity of this approach, it can be applied to any type of disclosure.

The data have the advantages of being relatively time-efficient to collect and code and can be used for large-scale samples. This might explain the popularity of this method among prior studies with 112 cases identified in the current systematic review of the literature. This approach is able to capture one type of disclosure at a time (e.g., voluntary, or mandatory) in contrast to other methods which fail to separate between these two types of disclosure such as disclosure survey and market-based measures. In addition, Leuz and Wysocki (2016) argue that this approach focuses on the existence of certain disclosures and hence disclosure can be precisely measured. Perhaps this is true when the focus of the measure is narrow, but still other disclosure activities might act as a substitute or a complement which need to be controlled for in the research design. When the focus of the measure is broad, however, at best they only partition companies into mutually exclusive groups (with some sort of order emerging if ordinal variables are employed), without any attempt to capture differences in the dimension of disclosure among companies that belong to the same group. In addition, coding could be subjective, in particular when weights are assigned, and hence results could be difficult to replicate, compare and generalize.

2.1.2 Disclosure index

A disclosure index[8] is a research instrument used to assess the extent of information reported in a disclosure vehicle(s) by a specific entity according to a list of selected items of information. The items of information could be quantitative or qualitative or both. It can be applied to different types of disclosures: mandatory or voluntary; or even to a specific type of

[8] Both the disclosure index method and textual analysis could be generally viewed as sub-types of content analysis because we are trying to draw valuable information from the data to the context of their use (Krippendorff, 1980). However, these two methods differ from each other in several aspects. For example, the unit of analysis under the disclosure index method could be figures or texts or both, while the unit of analysis under textual analysis is texts only. Using a disclosure index method, the researcher assesses whether disclosures have been made about some selected items of information, in contrast to the commonly used bag-of-words methods in textual analysis, for example, where the focus is on word count or word frequency, and where word sequence is ignored. Furthermore, while only human coding is used to develop disclosure scores using a disclosure index method, textual analysis can be conducted either manually or electronically. Therefore, we prefer to address these two methods separately.

disclosure such as management forecasts and segmental data. It does not count all items of information disclosed, but rather assesses whether disclosures have been made about the selected items of information through a close reading of the disclosure vehicle. Thus, the selection of items to include in the disclosure index is a key issue with this approach (Marston & Shrives, 1991). It can also be extended to assess the usefulness of information provided by awarding scores on an ordinal scale (e.g., 0/1/2/3) for disclosures of each item in a list (e.g., disclosures that contain quantitative data or report more information would receive a higher score than a minimal level of disclosure). However, the assignment of weights is itself subject to conceptual and procedural problems (e.g., Dhaliwal, 1980; Cooke & Wallace, 1989; Hodgdon et al., 2009; Cheung, Jiang, & Tan, 2010). The first use of such an index was by Cerf in 1961, and the method has been widely employed ever since (Marston & Shrives, 1991).

A disclosure index can be developed by the researcher (self-constructed disclosure indices) or developed externally by an academic or professional body (existing disclosure indices) such as Standard and Poor's transparency and disclosure scores, US Securities and Exchange Commission (SEC) ratings of the management discussion and analysis disclosure, the Center for International Financial Analysis and Research (CIFAR) disclosure scores, and the Joint Society of Management Accountants of Canada/University of Quebec and Montreal disclosure scores. Our review finds that the disclosure index approach is one of the most popular measures of disclosure; it is used in a variety of contexts indicating how flexible the method is. From our review of the literature, 50 cases were identified, including self-constructed disclosure indices as well as existing disclosure indices. A more detailed analysis reveals that most studies use self-constructed disclosure indices with data extracted from company reports and websites (e.g., Webb, Cahan, & Sun, 2008; Hodgdon et al., 2009; Melis et al., 2015; Mangena et al., 2016; Bazrafshan, Kandelousi, & Hooy, 2016), but some use the CIFAR index (e.g., Guedhami & Pittman, 2006; Han et al., 2012) or Standard and Poor's transparency and disclosure scores (e.g., Dargenidou et al., 2006; Ali, Chen, & Radhakrishnan, 2007).

Self–constructed disclosure indices have the advantage that they can be designed to fit the project (e.g., country, voluntary and/or mandatory disclosure, disclosure topic). However, the use of existing disclosure indices saves time, and results can be compared with the findings from other studies. Self-constructed disclosure index studies generally employ small samples owing to the labor-intensive data collection process, and results obtained are often difficult to replicate, compare and generalize (Hassan, Romilly, Giorgioni, & Power, 2009; Beyer et al., 2010). In addition, the construction of a disclosure index in prior studies often fails to explicitly account for the incremental information content of each new data item added to the index. Future research may develop an approach that can better capture the incremental information content of additional items of information disclosed by means of data reduction techniques such as factor analysis and principal component analysis. Furthermore, the appropriate method of aggregation is also of relevance here. For example, two companies may have disclosed completely different sets of information within the disclosure index and receive the same disclosure score.

2.1.3 Disclosure count

This approach counts the number of distinctive disclosures usually, but not necessarily, without evaluating their content or context. For example, the number of press releases (Francis, Nanda, & Olsson, 2008), the frequency of disclosure of non- GAAP earnings measures over a period of time (Marques, 2010), the number of online announcements

(Debreceny & Rahman, 2005), the number of segments reported by a firm (Kou & Hussain, 2007), and the number of internal control weaknesses reported by a firm in its Management Discussion & Analysis (Lu et al., 2011). This approach usually relates to particular types of disclosure such as conference calls, management forecasts, disclosure of non-GAAP numbers, information about material restatements and weakness, and segmental data (e.g., Rogers & Van Buskirk, 2009; Bergman & Roychowdhury, 2008; Marques, 2006; Lu et al., 2011; Kou & Hussain, 2007). It is frequently used in conjunction with a classification approach (e.g., Ge & McVay, 2005; Wasley & Wu, 2006; Francis et al., 2008; Levine & Smith, 2011).

Our systematic review shows that disclosure count is one of the most popular measures of disclosure with 36 cases identified from the articles analyzed. It is commonly used to measure the quantity of disclosure (Francis et al., 2008; Fu et al., 2012; Baginski, Clinton, & Mcguire, 2014), but it has also been used to assess other dimensions of disclosure such as quality (Sengupta & Zhang, 2015), the quantity and quality of disclosure (Wynn, 2008; Cuny, 2016) as well as the complexity (Kou & Hussain, 2007; Brochet et al., 2016), and credibility (Lu et al., 2011) of disclosures.

The data have the advantage of being relatively time-efficient to collect and code and the data can be used to study large scale samples. Disclosure count can provide new valuable information to the capital market, for example the management might hold frequent conference calls to update outside providers of funds on relevant up-to-date information about the business. However, it could also be induced by other managerial incentives such as management reputation.

2.1.4 Properties of reported earnings

This approach uses properties of reported earnings to measure financial reporting quality (e.g., Wang, 2006; Altamuro & Beatty, 2010; Chen et al., 2011; Kim & Venkatachalam, 2011; Koh et al., 2013; Filip et al., 2015). For example, while Krishnan, Wen, and Zhao (2011) use accruals quality and discretionary accruals to measure financial reporting quality, Altamuro and Beatty (2010) use various characteristics of reported earnings such as changes in loan-loss provision, earnings persistence, earnings predictability, benchmark beating behavior, and accounting conservatism. Lang, Lins, and Maffett (2012) measure firm transparency by less evidence of earnings management using properties of reported earnings, among other measures such as better accounting standards, higher quality auditors, more analyst following, and more accurate analyst forecasts.

Coding of these variables could be relatively easy and time-efficient and can be used for large-scale samples because these variables are constructed by means of economic modelling of available accounting figures rather than coding texts. Furthermore, both continuous and discrete proxies can be constructed. Dechow, Ge, and Schrand (2010) review different measures of earnings quality such as the magnitude of accruals, residuals from accrual models and earnings persistence among others, and reach no single conclusion on what earnings quality is, because ‘‘quality’’ is dependent on the decision context. Thus, different properties of reported earnings may capture different dimensions of quality and may be valid in different contexts (Berger, 2011). Dechow et al. (2010) also suggest that properties of reported earnings capture underlying earnings process with errors that are related to fundamental firms’ characteristics, real economic performance and the measurement of performance, a problem that is common for almost all measures of disclosure (Leuz & Wysocki, 2016). Dechow et al. (2010) further suggest that different proxies based on reported earnings are not equally affected by these factors which emphasizes that these measures are not measuring the same underlying construct. In addition, corporate financial disclosure is not limited to the accounting figures disclosed in the financial statements. It also includes qualitative information in the form of text (e.g., Core, 2001; Easley & O'Hara, 2004; Beyer et al., 2010). Thus, using accounting quality to proxy for the overall quality of corporate financial disclosure would be limited. Leuz and Wysocki (2016) consider attributes of reported earnings as narrow measures of corporate disclosure and reporting which have the advantages of being able to facilitate consistent measurement across firms, but these measures raise concerns about other disclosure activities that could serve as a substitute or a complement, which need to be controlled for in the research design. For example, firms can compensate poor earnings quality with enhanced voluntary disclosure. Even though, whether earnings quality could serve as a substitute or a complement of disclosure quality is still an empirical issue since some scholars suggest that they are substitutes (Mouselli, Jaafar, & Hussainey, 2012), while others suggest that they are complements (Francis et al., 2008).

2.1.5 Sentiment analysis

Scholars have used both quantitative and qualitative financial information to generate sentiments from corporate financial disclosure such as good/bad news disclosure and favorable/unfavorable disclosure. Some of the pioneer studies in this area include Clarkson, Kao, and Richardson (1994) and Skinner (1994). For example, Clarkson et al. (1994) measure voluntary disclosure of good (bad) news by positive (negative) changes in earnings in the current year compared to those of the previous year (or analysts' forecasts of earnings).

Alternatively, a firm is classified as good news if the cumulative residuals from the market model for the firm over the eight-month period after the annual report date are larger than zero. Ali et al. (2007) use the change in earnings per share from that of the same quarter in the previous fiscal year, deflated by stock price at the beginning of the quarter as a measure for voluntary disclosure of bad news (negative changes) and vice versa. Bamber et al. (2010) measure good/bad news disclosure by the difference between the management forecast and the most recent I/B/E/S consensus analyst forecast, deflated by the closing price one day prior to the management forecast date. If the difference is non-negative (negative), this is coded as good (bad) news, and 0 otherwise. Desir (2012) measures good/bad news disclosure based on changes in dividends, where an increase in dividends is considered good news, while a decrease is considered bad news.

In addition, both manual and automated textual analysis methods are used to measure the tone of a financial document (e.g. Skinner, 1994; Kothari et al., 2009; Li, 2010b; Rogers et al., 2011; Yekini et al., 2016). For example, Skinner (1994) constructs a measure of disclosure where disclosures are subjectively classified as good/bad/no news via manual textual analysis if the particular disclosure documents indicate that earnings will be better/worse/same compared to investor expectations. Rogers et al. (2011) use a dictionary-based text analysis program to quantify optimistic tone on a continuous scale. Kravet and Muslu (2013) measure the negative tone in risk disclosures by changes in companies' textual risk disclosures in the 10-K filings and provide evidence that textual risk disclosures reveal new information about corporate risks and uncertainties. Kearney and Liu (2014) survey different textual analysis methods applied on textual sentiment in the finance literature such as word lists, dictionary-based approach, and supervised machine learning. They suggest that corporate disclosure literature often use the term ‘tone’ to refer to textual sentiment, but sentiment in a broader term is not limited to positivity–negativity, but also include other affects such as strong–weak, and active–passive. Loughran and McDonald (2016) find that much of the literature uses a bag-of-words approach, where the word sequence is ignored, and the characters of a document is parsed into chunks of words, to measure document sentiment.

Sentiment analysis can be applied to both quantitative and qualitative financial information which indicates the flexibility of the method. Sentiments created from quantitative data, and textual sentiments developed using automated textual analysis are economical in terms of money, time and effort needed to implement the analysis, and can be applied to large samples. Both continuous and discrete proxies for disclosure can be constructed. However, the approach is inevitably subjective, hence the results could be hard to replicate and generalize, in particular with textual sentiments. In addition, while quantitative data can be distorted for several reasons such as earnings management, textual sentiments can be driven by different managerial incentives such as management reputation and impression management. In addition, textual sentiment analysis could be biased because of a managerial tendency to use positive words to frame negative statements (Loughran & McDonald, 2016). Perhaps future research should consider both quantitative and qualitative sentiments to control for this potential bias. Future research might also investigate how sentiments created using quantitative data compare with textual sentiments.

2.1.6 Textual analysis

Textual analysis is a research method to draw inferences from texts to the context of their use. Loughran and McDonald (2016) suggest the following hierarchy[9] of textual analysis: lexical, collocation, syntactic, semantic, pragmatic, and discourse. They claim that, to date, applications in accounting and finance are predominately in the initial phase of this interpretive sequence of lexical to discourse analysis.

We discuss textual analysis to the extent relevant to the current study and refer the reader to several excellent review studies on the subject (e.g., Jones & Shoemaker, 1994; Li, 2010a; Guo, Shi, & Tu, 2016; Loughran & McDonald, 2016; Grimmer & Stewart, 2013) for more in-depth discussion of the different methods employed under this approach. For example, Li (2010a) surveys recent empirical large-scale textual analysis studies by topical area (e.g., information content, earnings quality, market efficiency), and provides details on earlier manual-based textual analysis studies. Loughran and McDonald (2016) survey readability methods which attempts to measure the ability of the reader to decipher the intended message, and methods which typically focus on computationally extracting meaning from a collection of text such as bag-of-words methods and measuring document similarity. They address various methodological tripwires involved in these methods, highlight the challenges of separating out the concepts of business complexity and readability, and

[9] Loughran and McDonald (2016, pp.26-28) explain this hierarchy as following: the first step in analyzing text is *lexical* (bag-of-words) where the word sequence is ignored, and the characters of a document is parsed into chunks of words. Research interests at this stage are focused on some linguistic features such as word count, word difficulty and word frequency (Beattie, 2014). The second step, *collection*, is where meaning is derived from a collocation of words (or grams). For instance, the bigram of "going" and "concern" is an example where collocation is important, and if we extend this to *n*-grams, we can identify a collection of words as a sentence. Then using *syntactic* analysis, we can derive additional information by examining the grammatical structure of the sentence. Beyond syntax, *semantics* attempts to infer meaning within the context of the sentence. *Pragmatics* infers meaning from information immediately preceding and following the sentence, in addition to context provided by external knowledge. Finally, *discourse* is the attempt to derive meaning from the collective document.

emphasize the importance of replicability in the less-structured methods used in textual analysis. While, Guo et al. (2016) classify textual analysis methods into lexicon-based approach and machine learning approach, where the former includes readability measures and dictionary-based approach, and the later includes Naïve Bayes, Support Vector Machines, Semantic Analysis and Neural Network.

Textual analysis is commonly used to measure the quantity of disclosure (e.g., Chen, Cheng, Gong, & Tan, 2017a). However, the method is also used to assess other dimensions of disclosure such as quality (e.g., Chen, Miao, & Shevlin, 2015), complexity (e.g., You & Zhang, 2009; Filzen & Peterson, 2015) and horizon (Brochet, Loumioti, & Serafeim, 2015). The disclosure being studied can be mandatory, voluntary, or both, which highlights the flexibility of the method. Textual analysis can be partial or comprehensive. Partial textual analysis covers part of a document or selected items of information or key words. Comprehensive textual analysis covers a whole document.

Textual analysis can be conducted manually or automatically. One of the major limitations of manual textual analysis is that it is a labor-intensive data collection process, which inevitably tends to restrict the sample size employed (Beattie & Thomson, 2007). Therefore, in the 1980s, automated textual analysis emerged and has been commonly employed ever since (e.g., Frazier, Ingram, & Tennyson, 1984; Abrahamson & Amir, 1996; Smith & Taffler, 2000; Breton & Taffler, 2001; Schleicher, Hussainey, & Walker, 2007; You & Zhang, 2009; Brown & Tucker, 2011). Automated textual analysis is often accompanied by some element of manual textual analysis depending on the research method. Examples of studies that use automated textual analysis are Schleicher et al. (2007), You and Zhang (2009) and Elshandidy, Fraser, and Hussainey (2015), and examples of manual textual analysis studies are Linsley and Shrives (2006), Boesso and Kumar (2007), and Chen et al. (2017a).

Automated textual analysis is easy to use and economic in terms of the time, effort and financial resources needed to implement the method. It can be easily used to conduct a comprehensive textual analysis and to cover sizable samples. However, textual analysis is not problem–free. When implementing this approach either manually or automatically using the frequency of words or key words, all possible synonyms and words with multiple meanings should be included (Weber, 1990). Using inappropriate or insufficient key words could lead to over- or underestimation of a disclosure level. Additionally, using words or key words isolated from their context in the whole sentence does not provide a sound unit of analysis and may yield misleading results (Milne & Adler, 1999; Beattie & Thomson, 2007). Furthermore, coding (either manually or electronically) that is entirely based on a pre-defined word list without recourse to actual disclosure content may not be able to fully capture the construct under investigation, which limits the validity of the constructed measure of disclosure (Beattie & Thomson, 2007; Grüning, 2011; Loughran & McDonald, 2016). Moreover, the focus of this method is on reported qualitative information, which means that quantitative information well be ignored under this approach.

Attempts to extend this approach beyond lexical analysis include, but are not limited to, the analysis of phrases rather than words and semantic analysis. For example, Grüning (2011) uses an information-retrieval vector space model (VSM), a supervised machine learning tool, to automatically analyze phrases (n-grams) rather than words; he argues that this provides better unit of analysis and eliminates human involvement in the process. Using VSM, Grüning (2011) undertakes the coding of corporate disclosure in two phases: training and application. In the training phase, Grüning manually develops a comprehensive coding scheme based on a sample of representative annual reports, attempting to classify and quantify the diversity of corporate financial and non-financial disclosures. In the application phase, the coding scheme is automatically applied to a larger number of annual reports without human involvement to develop a disclosure score. Brown and Tucker (2011) provide another example of advancement in this area where they use VSM to measure changes in disclosure documents based on identifying semantic similarity. Changes in disclosure rather than disclosure levels could give us more meaningful insights about disclosure practice by removing boiler-plate disclosure for instance. However, the measure obtained is a summary of changes in a document and does not specify the nature of any changes in disclosure which have taken place (Berger, 2011).

2.1.7 Attributes of management forecasts

A management forecast is an item of forward-looking information, which management may provide in annual reports, interim reports, or elsewhere. This information may be quantitative (where a specific figure or range of figures is supplied) or qualitative (where a general direction or trend in company performance might be given). For example, management earnings forecasts available in the First Call database can take the following forms: point, range, one-sided directional, or confirming statements. They can be verified through actual earnings realizations, and hence they enable researchers to construct variables such as management forecast accuracy, error and bias. Recent studies also use management forecasts of cash flows, capital expenditures and store openings (e.g., Adhikari & Duru, 2006; Wasley & Wu, 2006; Cole & Jones, 2015) to construct their measure of disclosures.

Management forecasts have been used widely in the accounting literature to assess voluntary disclosure quantity and quality, especially studies from the US[10]. This may be because of the availability of these data in different databases such as that provided by First Call and the Dow Jones News Retrieval Service. Some studies only use attributes of management forecasts to assess the quality of voluntary disclosure (e.g., Yang, 2012; Bonsall et al., 2013; Cole & Jones, 2015; Kitagawa & Okuda, 2016; Zuo, 2016). While management earnings forecasts have the advantages of being concrete disclosure events, they are considered less comprehensive than other measures of disclosure such as AIMAR disclosure scores (Lang & Lundholm, 1996). In addition, management forecasts could be driven by different managerial incentives other than facilitating communication with external providers of funds such as management reputation and earnings management, which would affect the credibility of measures of disclosure developed from management forecasts (Kim & Park, 2012; Beyer & Dye, 2012; Cheng, Luo, & Yue, 2013). However, attributes of management forecasts are relatively easy and time-efficient to construct and can be used for large-scale samples. Also, both continuous and discrete proxies for disclosure can be constructed using attributes of management forecasts (e.g., Baginski & Rakow, 2012; Bonsall et al., 2013).

2.2 Non-disclosure-based approach

The second measurement approach views disclosure as a latent (unobservable) variable, and thus measures it through some other (non-disclosure-based) observable variables such as market-based data and the adoption of high-quality accounting standards.

[10] While management earnings forecast disclosure is voluntary in the US market, it is mandatory for Japanese companies listed on a stock exchange (Suto & Takehara, 2018).

These observable variables are assumed to relate to the underlying concept (disclosure) that needs to be measured.

Non-disclosure-based observable variables can be further classified into formative and reflective variables. The difference between formative and reflective variables is in the theorized direction of causality between the latent variable and the observable variables (e.g., Fayers & Hand, 2002; Jarvis et al., 2003). If the direction of causality is from the latent variable to the observable variables, and if changes in the latent variable are hypothesized to cause changes in the observable variables, then these measures are referred to as reflective variables. If the observable variables are hypothesized to cause changes in the latent variable, then they are referred to as formative variables. In the context of financial disclosure, possible examples of reflective variables are disclosure surveys and market-based measures of disclosure. This is because the direction of causality is hypothesized to be from corporate financial disclosure to these observable variables. Possible examples of formative variables are regulatory change, the adoption of high-quality accounting standards, and the use of American depositary receipts. This is because these observable variables are hypothesized to cause changes in corporate financial disclosure. Jarvis et al. (2003) provide decision rules for determining whether a measure is formative or reflective, although they note that answering the questions associated with these rules may be difficult and the answers may be contradictory. Although non-disclosure-based measures are less labor-intensive for researchers to develop because they do not require detailed analysis and coding of disclosure instruments and can be used for large-scale samples, their relationship with disclosure may be weak or bidirectional. In addition, using a reduced-form research design, that is not following the entire causal path between corporate disclosure and the variables of interest, makes the analysis susceptible to omitted variable bias, e.g. the change in the variable of interest could be triggered by other omitted confounding variables such as institutional changes and economic shocks (Leuz & Wysocki, 2016). Table 5 provides a summary of common non-disclosure-based measures identified in the current review of the literature.

<<Insert Table 5 about here>>

2.2.1 Formative measures

(i) Regulatory change that affects disclosure

Many prior studies use a regulatory change event to proxy for a change in disclosure quantity or quality or both. For example, Zhou (2007) investigates the link between information asymmetry and increased accounting disclosures following the adoption of new auditing standards using a dummy variable that takes the value of one if the observation is from the post-adoption period, and zero otherwise. Wang (2010) uses a dummy variable equal to zero for the years 1998 through 2001 and one for the years 2002 through 2005 to proxy for increased internal control disclosures mandated by the Sarbanes-Oxley Act (SOX). Leuz et al. (2008) analyze the effects of SOX on SEC deregistration and examine the causes and consequences of a significant and voluntary decrease in a firm's commitment to disclosure which they attribute largely to SOX. Bonaimé (2015) uses a categorical variable to proxy for increased transparency around the 2003 modification to SEC Rule 10b-18, which mandates enhanced disclosure of repurchase transactions. Other studies (e.g., Herrmann, Hope, & Thomas, 2008; Canace, Caylor, Johnson, & Lopez, 2010; Chen, Dhaliwal, & Xie, 2010) examine the consequences of Regulation Fair Disclosure, which prohibits the disclosure of material non-public information to selected groups or individuals such as financial analysts or institutional investors. These studies use a dummy variable to proxy for the quantity and quality of disclosure.

The method is easy to use and economical in terms of the time, effort and money consumed in constructing a proxy for a change in disclosure. Data to construct these variables either come from the event date or filings or databases containing information related to the event. However, the variables merely indicate that a change in disclosure either has/has not taken place, with no attempt to measure the size of this change. In addition, there is no attempt to assess the actual level of compliance with the regulatory change, which could be problematic; particularly in the absence of strong enforcement policies. Leuz and Wysocki (2016) suggest that the observed outcomes around a regulatory change are joint effects of that change and institutional complementarities such as the auditing supervisory agencies, and legal remedies. The impact of the institutional settings will also limit the ability to generalize the outcomes to other environments even if the causal relationship between a regulatory change and the variables of interest is correctly observed.

(ii) Voluntary use of GAAP (e.g., US GAAP or IFRS) to indicate higher disclosure (GAAP)

Several prior studies construct dummy variables about the voluntary adoption of GAAP which are used to proxy for higher disclosure (e.g., US GAAP or International Financial Reporting Standards [IFRS]) versus lower disclosure (local GAAP). For example, Van Tendeloo and Vanstraelen (2005) examine whether the adoption of IFRS is associated with lower levels of earnings management using a dummy variable that takes the value of one if the firm voluntarily adopts IFRS and zero otherwise; this dummy variable is used to proxy for enhanced financial reporting quality. Another example is Frino et al. (2013) who use the early adoption of IFRS in Italy to proxy for increased disclosure and examine its effect on stock liquidity. A further example is Wan–Hussin (2009) who use the early adoption of an accounting standard associated with greater disclosure, namely the disaggregation of accounting information by business segments to proxy for corporate transparency.

Data to construct the variable can be retrieved from databases, or researchers may need to inspect companies' annual reports. These data have the advantage of being relatively time-efficient to collect and code and can be used for large-scale samples. However, the use of a dummy variable only splits companies into two mutually exclusive groups where actual disclosure can still differ among the members of the same group.

2.2.2 Reflective measures

(i) Market–based measures

Market-based measures[11] have been used to proxy for disclosure quantity or quality in prior studies (e.g., Ascioglu et al., 2005; Rogers, 2008; Rogers & Van Buskirk, 2009; Reeb & Zhao, 2013). For example, Rogers (2008) uses changes in market liquidity to proxy for disclosure quality based on the argument that high-quality disclosure improves market liquidity. However, Berger (2011) notes that changes in market liquidity may arise for reasons other than changes in disclosure quality, that is the omitted variable problem. This problem can be eliminated by using control variables and validation tests, but the number of control variables needed might be sizeable. According to Berger (2011), Rogers' (2008) attempt to include controls provides some validation for his measure of disclosure.

[11] We only provide some examples of market-based disclosure measures; thus, this should not be interpreted as a complete list of these measures.

Market-based measures of disclosure have the advantage of being easily obtainable from databases and can be estimated for large samples. Also, they can be constructed using both discrete and continuous variables. However, these measures usually suffer from a lack of theoretical casual path linking them with disclosure. In addition, failure to integrate market efficiency into the discussion could be a fatal oversight (Verrecchia, 2001). Moreover, the availability of these measures will be limited to listed companies only which indicates potential selection bias. Furthermore, market-based measures are noisy measures of corporate financial disclosure because they are likely to capture both public and private information, financial and non-financial information, and information provided by the company and by a third party such as financial analysts and the media. They are also likely to capture not only a firm's disclosure practice but also its fundamental characteristics and performance.

(ii) Disclosure survey

A disclosure survey is an investigation of the perceptions of financial analysts, investors, or other user groups about firms' disclosure practices through questionnaires or interviews (e.g., Nikolaev & Van Lent, 2005; Daske & Gebhardt, 2006; Brown & Hillegeist, 2007; Glaum et al., 2013).

Perhaps the most common example of a disclosure survey in the empirical accounting literature is that conducted by the Financial Analysts Federation and the Association for Investment Management and Research (AIMR), where results of these surveys have been used as proxies for disclosure quantity and quality in many prior US studies (e.g., Dhaliwal, Khurana, & Pereira, 2011; Huang & Zhang, 2012; Ali, Klasa, & Yeung, 2014). Original scores about the importance of different disclosures can be also converted into a dummy variable (e.g., Brown & Hillegeist, 2007). However, these scores are now out of date, given that they were discontinued in 1997 after the fiscal year 1995 (Core, 2001). Since then, several regulatory changes have taken place in the US that may have an impact on firms' disclosure practices (Ertimur, 2007); the earlier survey evidence may therefore be redundant.

Other examples of studies using disclosure survey results in a European context are those of Daske and Gebhardt (2006) and Glaum et al. (2013). Both studies use quality scores extracted from competitions for the best annual reports run by business journals to proxy for disclosure quality.

Disclosure scores constructed by third-party organizations from surveys that they have conducted are not labor-intensive for a researcher because they are already completed. If the survey is applicable to a wide range of organisations, they can be employed for a sizable sample of firms compared to other research methods, such as the self-constructed disclosure index. Additionally, the scores obtained are usually constructed by using inputs from professional analysts familiar with the firms' disclosures, and thus claimed to enable direct measurement of disclosure quality (Glaum et al., 2013). The scores are also claimed to capture both the quantity and quality of disclosure since they provide useful information to expert users of this information (Leuz & Wysocki, 2016). However, this approach is based on analysts' (or other user groups') perceptions about firms' disclosure rather than actual disclosure (Lang & Lundholm, 1993; Beattie et al., 2004). Moreover, the ratings are potentially biased towards large firms which tend to feature prominently in the surveys. Additionally, the objectivity of the views of the investigated user group may be doubted, given that no one will know the user group's incentives to supply their ratings and the types of biases that may be present (Lang, 1999).

3. SOME EMIRICAL CHANLLENGES

In this section we discuss some measurement issues related to the development of a measure of disclosure. These are causal claims and reliability and validity assessment.

3.1 Causal claims

A major empirical issue that most prior empirical studies on corporate financial disclosure face is the causal claim, whether implicit or explicit, made between corporate financial disclosure and other observable variables. Such a claim must first be grounded in theory, that is the causal link between corporate financial disclosure and the observable variables is established in theory, and properly examined using suitable econometric methods. Scholars often borrow theories from economics, finance and psychology to establish a theoretical causal link between corporate financial disclosure and other observable variables (e.g., Healy & Palepu, 2001; Knooe, Seybert, & Smith, 2011). Gow, Larcker and Reiss (2016) view that accounting research needs a clear discussion of the theoretical causal mechanism that is being assumed for the research question and suggest researchers to use causal diagrams to be very transparent about such claims. However, a lack of a relevant theory that links corporate financial disclosure with other observable variables could be an issue. For example, Core (2001, p.449) suggests that tests of a link between disclosure quality and the cost of capital are joint tests of a theory linking disclosure quality to information asymmetry and a theory linking information asymmetry to a cost of capital. Even when a strong theoretical link between corporate financial disclosure and other observable variables can be established, a causal claim may still not be attainable if the variables are endogenous. Endogeneity occurs when the explanatory variable correlates with the error term of the estimation model. This will result in inconsistent and biased estimation of the coefficient of the explanatory variable, that is it does not converge to its true population value no matter how large the sample size is. This, in turn, means that the effect of the independent variable on the dependent variable cannot be interpreted. Some scholars shy away from inferring a causal link between disclosure and other observable variables, claiming that they are testing for association rather than causation. However, if endogeneity exists, even a simple correlation between the dependent variable and independent variable cannot be inferred because the magnitude of the effect can be wrong as well as its sign (Antonakis, Bendahan, Jacquart, & Lalive, 2010). Endogeneity occurs for a variety of reasons such as omitting important control variables from the estimation model, omitting fixed effects, omitting confounding variables, reverse causality, measurement errors in the independent variables, and model misspecification, among others (Ibid). For example, most disclosure studies either examine the determinants or consequences of disclosure but not both, which might fail to account for the full causal chain between disclosure and the variables of interest. This is called a reduced-form research design, which makes the analysis susceptible to endogeneity bias.

Examples[12] of prior studies which explicitly control for endogeneity bias in corporate financial disclosure literature are Nikolaev and Van Lent (2005), Lapointe–Antunes et al. (2006), Altamuro and Beatty (2010), Lim, Matolcsy, and Chow (2007), and Hope and Thomas (2008). For example, Nikolaev and Van Lent (2005) investigate two sources of endogeneity bias that affect the estimation of the relation between cost-of-debt capital and disclosure, namely: unobservable firm heterogeneity and observable omitted variables. They attempt to

[12] We were not specifically looking for discussions of endogeneity issue in prior studies when we did our survey, so this is not to be interpreted as a comprehensive list of studies that dealt with this issue in this review.

mitigate this endogeneity bias by relying on theory to identify additional variables correlated with both disclosure and cost-of-debt capital and by applying fixed effects estimation. Another source of endogeneity bias is reverse causality, which means that the relationship between corporate financial disclosure and other observable variables could be bi-directional. For example, Brown and Hillegeist (2007) control for the endogeneity bias caused by a reverse causality between disclosure quality and information asymmetry by employing a simultaneous equations approach.

Antonakis et al. (2010) provide an excellent review of the different sources of endogeneity bias and present methods that allow social scientists to test causal claims in non-experimental settings where randomization is not possible, such as simultaneous-equation models, Heckman selection models, regression discontinuity and difference-in-difference models, among others. Attempts to discuss sources of endogeneity bias in the accounting literature include Larcker and Rusticus (2010), Tucker (2010), Peel (2014; 2016), Gow et al. (2016), and Leuz and Wysocki (2016). For example, Larcker and Rusticus (2010) provide some insights into the use of instrumental variables and simultaneous equations by accounting researchers to mitigate the biases caused by endogeneity of the predictor variables. Table 1 in their study shows that disclosure research makes use of instrumental variables and identifies other accounting research areas such as auditing and earnings management. Gow et al. (2016) evaluate the different approaches accounting researchers adopt to draw causal inferences from observational data based on a review of all papers published in three leading accounting journals in 2014. They find that about 90% of these papers seek to draw causal inferences and that the most common estimation methods used in these studies include ordinary least-squares regression, difference-in-differences estimates, and propensity-score matching. However, they claim that the assumptions required for these methods to deliver credible estimates of causal effects are unlikely to be met in many applications that rely on observational data. They suggest that accounting research would benefit from more in-depth descriptive research, including a greater focus on the study of causal mechanisms and increased emphasis on the structural modeling of the phenomena of interest. Leuz and Wysocki (2016) discuss how all measures of corporate disclosure and reporting share a fundamental problem which is the need to separate a firm's reporting from its underlying economic characteristics and performance. However, corporate economic characteristics, disclosure policy and performance are co-determined by management strategy, that is management strategy identifies what a firm does and how it performs, and that the omission of this variable from the study methodologies causes an endogeneity problem. Leuz and Wysocki (2016) suggest structural equations modelling, among others, to address this problem. Tucker (2010) and Peel (2014; 2016) discuss selection bias in accounting research that is due to both observable and unobservable differences between the selected control firms and the sample firms in evaluating treatment effects and suggest methods to control both types of bias.

3.2 Reliability and validity assessment

In our search for measures of corporate financial disclosure, we observe that most studies tend to use a single measure of disclosure. Some studies use more than one measure for disclosure to examine different aspects of corporate disclosure or to check the robustness of their results. For example, Francis et al. (2008) use a disclosure index, as well as four categories of disclosure within the index, and finally, three alternative measures of voluntary disclosure: management forecast behaviour, number of firm-initiated press releases, and conference call activity.

However, whether a study uses one or more measures for corporate disclosure, and whatever the approach or scale used to develop it, it is constructed to approximate a theoretical concept that is difficult to measure directly. Hence, it is necessary to assess whether the measure of disclosure employed is a reliable and valid one. If the measure is not reliable and invalid, the resultant statistical inferences will not be meaningful. Although assessment of measures of disclosure is discussed to some extent in the accounting literature, a comprehensive analysis is lacking. Therefore, this section discusses the extent to which testing for reliability and validity is carried out within papers identified in our systematic literature review. Table 6 shows a list of the papers that have conducted some sorts of reliability and validity testing.

<<Insert Table 6 about here>>

3.2.1 Reliability Assessment

Reliability concerns the ability of a measurement instrument (e.g., a disclosure index) to produce consistent results in repeated trials. It also concerns the internal consistency of a measurement instrument, that is, the extent to which all parts of a measurement instrument are measuring the same thing (Carmines & Zeller, 1991). Reliability has three common forms: test-retest, inter-coder reliability, and internal consistency.

The test-retest measures the stability of the results obtained from a measurement instrument over time. In terms of textual analysis, for example, stability can be determined when the same text is coded more than once by the same coder (Weber, 1990, p. 17). Al-Akra and Ali's (2012) study is one example of how the test-retest approach can be used in manual coding for a self-constructed disclosure index. They rely on one coder in the coding process, and to reduce coding error, the annual reports were screened twice with the voluntary disclosure checklists.

Reproducibility or inter-coder reliability refers to the extent to which content classification produces the same results when the same text is coded by more than one coder (Weber, 1990, p. 17). Inter-coder reliability can be measured by the coefficient of agreement (e.g., Al-Shammari et al., 2008), which is the ratio of the number of pairwise inter-judge agreements to the total number of pairwise judgements (Beattie et al., 2004, p. 214). The higher the coefficient obtained, the higher the reliability of the measurement instrument. Because this measure does not consider the likelihood of random agreement between the coders, it is not perceived as an adequate measure of inter-rater reliability unless discrepancies between the coders are scarce or the discrepancies have been analyzed and any differences have been resolved (e.g., Rogers & Grant, 1997; Milne & Adler, 1999). To overcome the problem of random agreement between the coders, other measures including Scott's pi (e.g., Linsley & Shrives, 2006; Abraham & Cox, 2007), Krippendorff's alpha (e.g., Boesso & Kumar, 2007), Cohen's kappa (e.g., Hooghiemstra, 2010), and Leigh's lambda are used to test for inter-coder reliability (for more details, see Milne & Adler, 1999).

The third form of reliability is internal consistency. Litwin (1995, p. 21) describes internal consistency as 'an indicator of how well the different items measure the same issue. This is important because a group of items that purports to measure one variable should indeed be clearly focused on that variable'. For example, Hassan et al. (2009), Cormier et al. (2010), and Elshandidy and Shrives (2016) use Cronbach's alpha, which is a measure of interitem correlation, to assess the internal consistency of their measures of disclosure. Cheng and Courtenay (2006) compute pairwise parametric and non-parametric correlations between all the components of their disclosure index to assess internal consistency. Similarly, Kelton and Yang (2008) assess the correlation between the categories of their internet financial reporting index.

The low level of reliability testing identified within our review is consistent with research by Beattie and Thomson (2007), who report that reliability issues do not appear to be addressed in most intellectual capital disclosure studies which they examined. Reliability tests are mainly performed in studies that use a disclosure index and manual textual analysis. These types of disclosure measures are susceptible to coder error and judgement. However, many studies with no apparent reliability testing use a disclosure index or other variables obtained from company disclosures. Other measures of disclosure are based on third-party data with less room for coder error and judgement, such as market-based measures of disclosure. We recommend that researchers should consider the importance of conducting reliability tests of disclosure measures in future studies, when measures of disclosure are subject to coder error and judgement.

3.2.2 Validity Assessment

Validity is defined as 'the extent to which any measuring instrument measures what it is intended to measure' (Carmines & Zeller, 1979, p. 17). There are three common types of validity scrutinised in disclosure studies: content, criterion, and construct.

The first type of validity is content validity. This is assessed by seeking subjective opinions or judgements from non-experts and/or professionals (hence some refer to it as face validity) about how well the instrument measures what it is intended to measure. In our systematic review, we find that most cases of content validity testing are conducted in disclosure index and textual analysis studies. Not surprisingly, these studies use measures of disclosure that are subject to judgement; hence the authors seek reassurance about the face validity of their measurements of disclosure. A typical example is Patelli and Prencipe (2007), who explain that the inclusion of an item in their disclosure checklist is based on a prior study and is subject to amendment to suit the country in the investigation. They then consult with three experienced auditors and three financial analysts to test its suitability for the Italian setting that they are examining. However, this type of validity is never seen as sufficient when concluding about the validity of a measure. This may be because of concerns about users' perceptions regarding their own use of the information (Dhaliwal, 1980).

Criterion validity is a measure of how well one instrument compares with another instrument or "predictor" (Litwin, 1995, p. 37). Criterion validity assesses if there is a significant correlation between a measure and an external criterion (a desirable outcome). The higher the magnitude of the correlation coefficient, the more valid this instrument or measure is for this criterion. There are two types of criterion validity: concurrent and predictive. The difference between them is the time horizon considered: concurrent validity concerns the correlation between a measure and the criterion at the same time, whereas predictive validity concerns the correlation between a future criterion and the relevant measure. For example, Boesso and Kumar (2007) test the criterion validity of their measure of voluntary disclosure by correlating the number of observations on social perspectives obtained through their textual analysis with the number of awards received by the company. They argue that the greater the emphasis of a company on social activities, the greater the likelihood of being recognized in the form of awards for stakeholder communication by independent evaluators. Grüning (2011) and Ernstberger and Grüning (2013) provide another example where their measures of disclosure correlate negatively with measures of information asymmetry, that is the desired outcomes of enhanced disclosure is to reduce information asymmetry. However, criterion validity is less likely to be used when assessing the validity of social science measures. This is because most social science measures represent theoretical concepts for which there are no known criterion variables available for comparison. The more abstract the concept, the less likely one is to discover an appropriate criterion for assessing a measure of it (Carmines & Zeller, 1979, p.20). Therefore, it is not surprising that in our systematic review we find relatively few examples of this test among the studies considered.

In contrast to both content validity and criterion validity, construct validity has generalized applicability in the social sciences. 'It is concerned with the extent to which a particular measure relates to other external measures consistent with theoretically derived hypotheses concerning the concepts (or constructs) that are being measured' (Carmines & Zeller, 1979, p. 23). Therefore, testing for the construct validity of a measure of disclosure involves three steps: (i) to specify the links between the measure of disclosure and some theoretically related external variables, (ii) to test this theoretical links empirically, and (iii) to explain how the empirical evidence clarifies the construct validity of the measure of disclosure, which requires a pattern of consistent findings with prior studies. For example, Blanco et al. (2014) examine the association between their measure of the quantity of segment disclosure and common control variables, such as firm size, firm age, profitability, and leverage, and obtain results that are largely consistent with prior studies, to provide evidence on the construct validity of their measure of disclosure. Additionally, according to Weber (1990, p. 19), 'a measure has construct validity to the extent that it is correlated with some other measures of the same construct[13]', provided that these measures are proven to be reliable and valid measures of that construct. For example, Ernstberger and Grüning (2013) show that their measure of disclosure has construct validity with respect to other disclosure rankings; its association with the AIMR rating, Standard & Poor's transparency disclosure score and other rating methods is significant.

Although in our systematic review we find some evidence of validity testing, future researchers should carry out validity tests as a matter of course, otherwise the link between their proposed measures and corporate financial disclosure might be wrong or misleading. Overall, Table 6 shows that both the disclosure index and textual analysis methods are heavily scrutinised for their reliability and validity as measures for financial disclosure, which justifies more reliance being placed on these measures of disclosure in future studies.

4. DISCUSSION AND RECOMMENDATIONS

The framework for disclosure measurement developed in this study identifies two approaches: (i) a disclosure-based approach that focuses on investigating actual disclosure, operationalizes the concept of disclosure by disaggregating it into its main dimensions such as the quantity and quality of disclosure, and develops methods to measure them, such as the disclosure index and textual analysis, and (ii) a non-disclosure-based approach that deals with disclosure as a latent (unobservable) variable that we indirectly observe through the values of another observable variable(s). These non-disclosure observable variables can be

[13] In our view, this definition of construct validity could be seen as a narrower application of the former, as Weber limits the potential external variables to other measures of the same construct only.

further classified into formative variables and reflective variables, depending on whether the measure is a determinant or a consequence of disclosure. Our systematic review shows that most prior studies tend to use disclosure-based measures rather than non-disclosure-based measures when investigating disclosure. This is because disclosure-based measures have concrete links to actual disclosure and their reliability and validity can be extensively assessed – as in prior studies. Additionally, most measures of disclosure uncovered in our review are discrete. Discrete measures can be bivariate (0/1 dummies) or multivariate (e.g., disclosure index). Some non-disclosure-based measures are continuous (e.g., market liquidity). However, most disclosure proxies merely rank companies relative to each other, that is, there is no true zero point. Thus, these measures do not possess the characteristics of a ratio scale, but at best only possess the characteristics of an interval scale. Other measures are merely ordinal. Whether a measure is discrete or continuous is important because it impacts the type of econometric analysis that can be employed on the data.

We find that traditional methods for measuring disclosure through direct investigation of a disclosure vehicle such as the disclosure index method continue to dominate the literature, with the classification approach being particularly popular. This prevalence seems to be motivated by ease of coding and the ability to consider large samples. However, the classification approach only sorts companies into mutually exclusive groups with no attempt to study variations in the disclosure attribute within each group. To the best of the authors' knowledge, no new methods are observed that investigate a disclosure vehicle directly, but new directions in the application of automated textual analysis are observed. For example, Grüning (2011) uses VSM, a supervised machine learning tool, to analyze phrases rather than words and to replicate human coding, while Brown and Tucker (2011) use VSM to measure document similarity. Further developments in the artificial intelligence area are expected to induce improvement in automated textual analysis by providing different units for investigation and new directions of analysis. For example, the application of the concept of deep learning in natural language processing could enhance machine coding of textual sentiment analysis and eliminate human involvement (e.g., Araque, Corcuera-Platas, Sánchez-Rada, & Iglesias, 2017; Chen, Xu, He, & Wang, 2017b). However, automated textual analysis methods will never replace careful and close reading of texts given the complexity of language and research interests in both the intended and unintended information conveyed by the text (Grimmer & Stewart, 2013; Loughran & McDonald, 2016). Another common feature of traditional methods is that they focus on individual items of information, key words or phrases rather than the inter-relationship between them. New visualization methods in qualitative data analysis software, such as tag clouds, tree maps, cluster analysis, and word trees, will help researchers to see the patterns and connections in their data and gain more insight about the disclosures.

The non-disclosure-based measurement approach considers a range of observable variables that are related to financial disclosure, such as market-based measures. The non-disclosure-based measures are used to reflect on the different dimensions of financial disclosure such as its quality and quantity. The measures are relatively less labor-intensive for researchers because these they do not require detailed analysis and coding of the disclosure instruments. Data are mostly retrieved and coded from databases, thus enabling the usage of large-scale samples. This may be a pragmatic response to the preference given to large samples by US–based journals. However, the link between these observable variables and financial disclosure may be weak or bidirectional, thus they should be treated with caution.

In addition, an estimation model that involves these variables is likely to suffer from endogeneity bias for different reasons such as reduced-form research design.

We also discuss some empirical challenges related to causal claims and the reliability and validity assessment of measures of disclosure. To make a causal claim between a measure of disclosure and other observable variables, a full theoretical causal path must be grounded in theory and properly examined using suitable econometric methods. However, the theoretical link between disclosure and other observable variables might be weak or bidirectional and the research model might be susceptible to endogeneity bias. If endogeneity exists, scholars must deal with it, otherwise their results cannot be interpreted. Antonakis et al. (2010) provide an excellent review of the different sources of the endogeneity problem and present methods that allow social scientists to test causal claims in non-experimental settings where randomization is not possible. In addition, the Granger causality test might statistically help to detect the direction of causation (Gujarati, 2010) for temporal data, but the results of this test are sensitive to the number of lags included. While there are some attempts to discuss sources of endogeneity bias in accounting research in general (e.g., Larcker & Rusticus, 2010; Tucker, 2010; Peel, 2016; Gow et al., 2016; Leuz & Wysocki, 2016) to date, a comprehensive review of causal claims in corporate financial disclosure literature is lacking. Due to the gravity of this issue and how false inferences from empirical studies could impact business practice and policy formulation at firm level and national and international levels, future research might consider reviewing causal claims in prior empirical financial disclosure studies and their methodological rigor.

Finally, we document a low level of reliability and validity testing within papers identified in our systematic literature review. Reliability and validity tests are mainly performed in studies employing either textual analysis or the disclosure index method to measure disclosure. Furthermore, these two methods have the advantages of being disclosure-based and flexible measures of disclosure; hence they could be considered superior to other measures of disclosure. However, 'reliability' and 'validity' are typically perceived as inversely related (Deffner, 1986). For instance, while human coding shows greater validity because coding can be linked to the underlying construct, it is subject to judgement and coding errors which could reduce its reliability. Therefore, while validity assessment will continue to be essential for all measures of financial disclosure in future research because they are developed to measure a construct that cannot be measured directly, reliability assessment will only be an issue for the measures that are subject to coders' judgment and errors. In addition, researchers should be cautious because validity is context-specific, that is what could be a valid measure for corporate financial disclosure in one context might be invalid in a different context.

A current phenomenon of research into corporate financial disclosure is that it often fails to state explicitly the dimension of disclosure it is investigating (e.g., quantity, quality, tone, prominence, etc.). This is problematic because different measures of disclosure may only be appropriate for investigating specific dimensions of disclosure. For example, while textual analysis could be a suitable method to measure the extent of disclosure, a classification method would be more suitable to examine the prominence given to certain disclosures. Additionally, different inferences can be drawn about different dimensions of the same type of disclosure. For example, some prior studies use disclosure quantity (e.g., Cheung et al., 2010; Mouselli et al., 2012) as a proxy for disclosure quality, although the quantity and the quality measures may lead to different rankings for one sample of companies. In addition, the concept of disclosure quality is subjective and what constitutes quality is still a research question (e.g., Core, 2001; Botosan, 2004; Beattie et al., 2004). Also, more disclosure (quantity) can come at the cost of quality if it hinders readability and increases complexity. Therefore, future researchers should be explicit about the exact dimension(s) of financial disclosure they are investigating and whether the measure of disclosure being employed is, in fact, measuring what it seeks to measure. Additionally, some methods or measures of disclosure are limited in their scope (either numbers or texts) such as textual analysis which focuses on analyzing texts, whereas properties of reported earnings approach focus on accounting numbers only. Therefore, inferences obtained from such metrics should be qualified to reflect their limitations. Furthermore, prior studies have tried to develop proxies for the different dimensions of financial disclosure such as transparency, complexity, quantity, quality, tone, etc. However, a comprehensive list of the necessary and sufficient dimensions of disclosure is lacking, which future research might seek to develop.

Whether a measure of disclosure can be used to assess voluntary or mandatory disclosure is another issue that a researcher needs to consider. Most disclosure-based measures have the flexibility to be applied to different types of disclosure. However, while manual coding can possibly account for different types of disclosure being studied, machine coding is less able to distinguish between the two types of disclosure based on a search of some key words or targeted phrases. This problem can be mitigated if the document is only covering one type of disclosure. On the other hand, some measures are linked to a specific type of disclosure such as the properties of reported earnings, which relate to financial reporting regulations. Others, such as a disclosure survey (Beyer et al., 2010), can capture both voluntary and mandatory disclosures. Therefore, future researchers should be clear about their choice of disclosure measure and consider whether it is solely identifying the specific type of disclosure they aim to measure.

Another related issue to consider is the time orientation of information disclosure, that is whether it is historical information, concurrent information or forward-looking information. Some measures of disclosure can be used to reflect on these different aspects of disclosure such as the disclosure index and textual analysis methods. Other measures of disclosure can only reflect on a specific type of information. For example, attributes of management forecasts are measures for forward-looking information, while properties of reported earnings are reflecting on historical information. Thus, understanding the time orientation of information disclosure is important to define a suitable measure for disclosure. Additionally, the content of disclosure could vary, which might cause different proxies of the same attribute of the same type of disclosure to behave differently in empirical analysis. For example, Francis et al. (2008) find that various measures of the level of voluntary disclosure (self-constructed disclosure index, management forecast behavior, press releases, conference calls) do not produce consistent results in their relations with earnings quality and cost of capital. They suggest that these different measures of the extent of voluntary disclosure are likely to capture different forms of voluntary disclosure (forward-looking information supplied by management; contemporaneous discussion of results in conference calls; an overall index of voluntary disclosure in mandatory filings) that have different content and are likely to be motivated by different managerial incentives.

Given the several aspects of financial disclosure that are at play, and the considerable number of measures of financial disclosure identified in our paper, there is a scope for further research into how the different measures, all other things being equal, compare with one another. It would be interesting to obtain or calculate as many proxies of disclosure as possible for a carefully selected sample of companies. Analysis could then be carried out to see how the different proxies compare in one period and over time. Future research might also investigate the interactions between the different dimensions, the different time orientation and the different types of disclosure, their determinants and consequences, and how they compare. For example, how does the quality of concurrent voluntary disclosure compare to the quality of forward-looking voluntary disclosure? And which one is better able to explain changes in firm value for example, and why? How does the tone or complexity of concurrent voluntary disclosure compare to that of concurrent mandatory disclosure? Which type of information disclosure tends to be more complex and why?

To conclude, the concept of corporate financial disclosure is inherently complex. Corporate financial disclosure has different types (mandatory and voluntary), different vehicles (e.g., company reports, conference calls and press release), different time orientations (e.g., historical data, concurrent data, forward–looking data), different dimensions (e.g., quality, quantity, tone, and prominence), and different formats (e.g., numbers and texts). The different aspects of corporate financial disclosure are probably impossible to unequivocally and conclusively determine. Consequently, all measurement, to some extent, is inevitably subjective and partial. This paper identifies 11 common measures of disclosure that a researcher can choose from depending on the purpose of study, data availability and economic factors in terms of time, effort and money needed to develop a measure of disclosure. However, more work is needed to develop innovative and diverse research methods that can capture the richness of the concept of financial disclosure. New methods need not be sophisticated if simple methods can address the research question(s).

Scholars introducing new methods to the literature should explain them in detail to make their results replicable.

ACKNOWLEDGEMENT

The authors wish to thank two anonymous referees, Emeritus Professor Pauline Weetman, University of Edinburgh, Dr Peter Romilly, Ecmetrika Consultancy & Research, Professor David M. Power, University of Dundee, and Professor Louise Crawford, Robert Gordon University for their constructive and detailed feedback. Remaining errors are the responsibility of the authors.

Total	280	100

Table 3. Common proxies for financial disclosure

This table shows the extent of commonly used measurements for disclosure in prior studies and provides some exemplars.

Measurement	Approach	Count	%	Exemplars
Classification approach	DB	112	30.19	Bowen, Davis, and Matsumoto (2005); Marquardt and Wiedman (2007); Hollander, Pronk, and Roelofsen (2010); Gillan and Panasian (2014); Cannizzaro and Weiner (2015).
Disclosure index	DB	50	13.48	Dargenidou, Mcleay, and Raonic (2006); Guedhami and Pittman (2006); Hodgdon, Tondkar, Adhikari, and Harless (2009); Han, Kang, and Yoo (2012); Melis, Gaia, and Carta (2015); Mangena, Li, and Tauringana (2016).
Disclosure count	DB	36	9.70	Debreceny and Rahman (2005); Bergman and Roychowdhury (2008); Lu, Richardson, and Salterio (2011); Fu, Kraft, and Zhang (2012); Kirk and Vincent (2014); Brochet, Naranjo, and Yu (2016).
Properties of reported earnings	DB	34	9.16	Wang (2006); Altamuro and Beatty (2010); Chen, Hope, Li, and Wang (2011); Kim and Venkatachalam (2011); Koh, Rajgopal, and Srinivasan (2013); Filip, Labelle, and Rousseau (2015).
Sentiment analysis	DB	34	9.16	Kothari, Li, and Short (2009); Li (2010b); Bamber, Hui, and Yeung (2010); Rogers, Van Buskirk, and Zechman (2011); Kravet and Muslu (2013); Yekini, Wisniewski, and Millo (2016).
Textual analysis	DB	31	8.36	Boesso and Kumar (2007); Abraham and Cox (2007); Grüning (2011); Brown and Tucker (2011); Miihkinen (2012); Filzen and Peterson (2015)
Attributes of management forecasts	DB	29	7.82	Yang (2012); Bonsall, Bozanic, and Fischer (2013); Cole and Jones (2015); Kitagawa and Okuda (2016); Zuo (2016).
Regulatory change that affects disclosure	NDB	21	5.66	Zhou (2007); Leuz, Triantis, and Wang (2008); Wang (2010); Arping and Sautner (2013); Bonaimé (2015); Cho (2015).
Market-based measures	NDB	10	2.70	Ascioglu, Hegde, and McDermott (2005); Rogers (2008); Rogers and Van Buskirk (2009); Reeb and Zhao (2013).
Disclosure surveys	NDB	7	1.89	Nikolaev and Van Lent (2005); Daske and Gebhardt (2006); Brown and Hillegeist (2007); Huang and Zhang (2012); Glaum, Baetge, Grothe, and Rster (2013).
Use of GAAP (e.g., US GAAP or IFRS) to indicate higher disclosure	NDB	7	1.89	Van Tendeloo and Vanstraelen (2005); Lapointe–Antunes, Cormier, Magnan, and Gay-Angers (2006); Wan-Hussin (2009); Frino, Palumbo, Capalbo, Gerace, and Mollica (2013).
Total number of common proxies of disclosure		371*	100	

*. Some studies use more than one measure of disclosure, therefore the total number of measures of disclosure employed in prior studies exceeds the number of studies covered in our systematic review, that is 280 studies. DB (NDB): disclosure-based (non-disclosure-based) measurement approach.

Table 4. Summary of common disclosure-based measures of financial disclosure

This tables provides a summary of common disclosure-based measures of corporate financial disclosure covered in this review. It shows how each measure reflects on a specific dimension(s) of disclosure and the common pros and cons. It also shows whether the measure of disclosure is discrete or continuous which can impact the type of econometric analysis that can be employed.

Measurement	**Dimension of disclosure**	**Type of variable**	**Main Strengths and weaknesses**
Classification approach	It is used to measure different dimensions of disclosure	Discrete	*Pros.* The approach is flexible and can be applied to different types and dimensions of disclosure. It can capture one type of disclosure at a time. It is easy and economical to use in terms of the time, effort and money consumed, and can be applied to large samples. *Cons.* It merely classifies the data to mutually exclusive categories without any attempt to capture differences in the dimension of disclosure among the members of the same group. Coding could be subjective, and hence results could be difficult to replicate, compare and generalize.
Disclosure index	It is typically used to measure the quantity and/or quality of disclosure	Discrete	*Pros.* The measure fits the project well. The method is flexible and can be applied to different types of disclosure. It can also capture one type of disclosure at a time. *Cons.* Self-constructed disclosure index is a subjective method for measuring disclosure, hence the results are hard to replicate and generalize. It is also a labor-intensive and time-consuming method which results in utilizing small samples.
Disclosure Count	It is commonly used to measure disclosure quantity	Discrete	*Pros.* The approach is flexible and can be applied to different types of disclosure. It is easy and economical to use in terms of the time, effort and money consumed, and can be applied to large samples. *Cons.* It merely counts the number of disclosures being made without any attempt to investigate their content or context. It could also be driven by different managerial incentives other than facilitating communication with external providers of capital.
Properties of reported earnings	They are usually used to measure the quality of financial reporting	Discrete or continuous	*Pros.* Both continuous and discrete proxies for disclosure can be constructed. Coding is relatively easy and time-efficient and can be used for large-scale samples. Measures can facilitate consistent measurement across firms. *Cons.* The quality of financial reporting is not limited to accounting quality only. Different properties of reported earnings may capture different dimensions of quality (Berger, 2011). Other disclosure activities that could serve as a substitute or a complement.
Sentiment analysis	It is usually used to measure the tone of financial disclosure	Discrete or continuous	*Pros.* The approach is flexible and can be applied to both quantitative and qualitative financial information. It is easy and economical to use with quantitative data and can be applied to large samples. Both continuous and discrete measures for disclosure can be constructed. *Cons.* The approach is inevitably subjective. While quantitative data can be distorted, textual sentiments can be driven by different managerial incentives such as management reputation.
Textual analysis	It is frequently used to measure the quantity and quality of disclosure	Discrete	*Pros.* The approach is flexible and can be applied to different types of disclosure. Automated textual analysis is particularly easy and economical to use in terms of the time, effort and money consumed, and can be applied to large samples. *Cons.* The use of key words does not provide a sound unit of analysis. Using inappropriate or insufficient key words could lead to over- or underestimation of disclosure level. In addition, coding based on a pre-defined list of words that is developed in isolation of actual disclosure texts may not be able to fully capture the construct under investigation, which limits the validity of the constructed measure of disclosure.

Attributes of management forecasts	They are traditionally used to measure the quantity and quality of voluntary disclosure for the US market.	Discrete or continuous	*Pros.* Both continuous and discrete measures for disclosure can be constructed. Coding is relatively easy and time-efficient and can be used for large-scale samples. *Cons.* Management forecasts are relatively less comprehensive measures of disclosure and they could be subject to earnings management, which would affect the quality of these forecasts as measures of disclosure.

Table 5. Summary of common non-disclosure-based measures of financial disclosure

This tables provides a summary of common non-disclosure-based measures of corporate financial disclosure covered in this review. It shows how each measure reflects on a specific dimension(s) of disclosure and the common pros and cons. It also shows whether the measure of disclosure is discrete or continuous which can impact the type of econometric analysis that can be employed.

Measurement	**Dimension of disclosure**	**Type of variable**	**Main Strengths and weaknesses***
Formative measures			
Regulatory change that affects disclosure	It is often used to proxy for a change in the quantity or quality of disclosure	Discrete	*Pros*. The approach is easy to use and economical in terms of time, effort and money consumed in constructing a proxy for disclosure. *Cons*. The variable merely indicates a change in disclosure, with no attempt to measure the size of that change. There is no attempt to assess actual level of compliance with the regulatory change, which could be problematic, particularly in the absence of strong enforcement policies.
Voluntary use of GAAP (e.g., US GAAP or IFRS) to indicate higher disclosure	It is generally used to proxy for higher level of disclosure quantity and/or quality	Discrete	*Pros.* It is a relatively easy and time-efficient variable to construct and can be used for large-scale samples. *Cons.* It only divides the sample into two mutually exclusive groups where actual disclosure can still differ among the members of the same group.
Reflective measures			
Market-based measures	They are frequently used to proxy for the quality of disclosure	Discrete or continuous	*Pros.* These measures are easily obtainable from databases and can be used for large samples. Also, they can be constructed using both discrete and continuous variables. *Cons.* However, these measures usually suffer from a lack of theoretical casual path linking them with disclosure and are likely to be noisy measures of disclosure.
Disclosure surveys	They are usually used to proxy for disclosure quantity and quality	Discrete	*Pros.* Disclosure scores are ready-made by professional analysts and can be obtained for sizable samples. *Cons.* The scores reflect analysts' perceptions about firms' disclosure policies, rather than direct investigation of actual disclosure practices. Analysts' ratings are profoundly geared towards large firms. This approach is subject to measurement bias because the disclosure score created could capture not only the disclosure practice of a company but also its fundamental characteristics and performance.

*These measures share some common cons such as a reduced-form research design and their relationship with disclosure could be bidirectional.

Table 6. The extent of conducting reliability and validity tests in prior studies

This table shows a list of the studies that have conducted some sorts of reliability and validity testing on their measures of disclosure, so studies that have not explicitly done so are not listed in this table.

Test	**Disclosure Index**	**Textual analysis/ *Textual Sentiment Analysis***	**Other Measures of Disclosure**
Test-retest	Al-Akra and Ali (2012).	Boesso and Kumar (2007).	
Inter-coder reliability	Owusu-Ansah and Yeoh (2005); Cheng and Courtenay (2006); Al-Shammari, Brown, and Tarca (2008); Cheung et al. (2010); Cormier, Aerts, Ledoux, and Magnan, (2010); Melis et al. Anomaly

ABSTRACT

We document that earnings acceleration, defined as the quarter-over-quarter change in earnings growth, has significant explanatory power for future excess returns. These excess returns are robust to a wide range of previously documented anomalies and a battery of risk controls. The future return predictability appears to be consistent with investors assuming a seasonal random walk model for quarterly earnings and missing predictable implications of earnings acceleration for future earnings growth. Finally, the excess returns from the basic earnings acceleration strategy can be enhanced further by focusing on profit firms, low earnings volatility firms and on specific patterns of earnings acceleration.

1. Introduction

Earnings acceleration, or the change in earnings growth, has anecdotally been discussed as a viable trading strategy in the popular press.[1] Despite anecdotal references to its use in the investing world, and in contrast to the vast number of studies on the capital market implications of earnings growth (Kothari, 2001; Lakonishok et al., 1994; Dechow and Sloan, 1997; Bernard and Thomas, 1989; Akbas et al., 2017), earnings acceleration has received limited research attention. In this study, we examine the implications of earnings acceleration for future stock returns.

We measure earnings acceleration as the change in earnings growth from one quarter to the next, where earnings growth is the scaled change in earnings over the corresponding quarter a year ago. Using a sample of 377,907 observations spanning

[1] For example, American Century Investments appears to actively focus on companies with accelerating earnings (see http://americancenturyblog.com/wp-content/uploads/Chart-of-the-Week-Mar.-4-2012-Earnings-Acceleration.pdf). Investor's Business Daily, a historically influential newspaper targeted at investors, promotes a stock picking formula that incorporates "earnings acceleration" (see O'Neil, 1999). Several additional examples are cited in Cao et al. (2011).

8,824 different firms and 176 fiscal quarters from 1972 to 2015, we find that earnings acceleration is a significant predictor of future stock returns.[2] A trading strategy that involves going long in the top decile of quarterly earnings acceleration and short in the bottom decile of earnings acceleration produces large market-adjusted returns, both in one-month and quarter-long trading windows that start two days after an earnings announcement. We find market-adjusted returns of 1.8% (3.4%) over the month-long (quarter-long) window, which translates to annualized returns in excess of 23% (14%). The significant excess returns persist even when low priced stocks (less than $5) and/or low capitalization stocks (up to $0.5 billion) are excluded from the trading strategy. While the primary trading strategy involves buying/selling stocks two days after the earnings announcement, we still obtain significant excess returns when a conservative trading strategy involving calendar month rebalancing is adopted.

We conduct a battery of tests to rule out two potential explanations for the excess returns: (a) the returns are a manifestation of an already known anomaly, and (b) the analysis omits a risk factor. First, to rule out the known anomaly explanation, we demonstrate that the excess returns are robust to the inclusion of several known anomalies, namely post-earnings announcement drift (PEAD, Bernard and Thomas, 1990), profit trend anomaly (Akbas et al., 2017), combination of known mispricing factors (Stambaugh and Yuan, 2017), gross profit anomaly (Novy-Marx, 2013), accrual anomaly (Sloan, 1996), past earnings volatility (Cao and Narayanamoorthy, 2012), return momentum (Jegadeesh and Titman, 1993), total asset growth anomaly (Cooper et al., 2008), as well as the size and book-to-market anomalies. Second, to preclude a missing risk factor explanation, we document the robustness of our results to the use of Fama-French three-factor and Carhart four-factor adjusted returns. More recently, Fama and French (2015) have proposed a five-factor model that augments the previous three-factor model with two additional factors − investment and profitability. The results are robust to the use of Fama-French five-factor adjusted returns as well. Additionally, the trading strategy spanning 176 quarters rarely produces losses − for a risk explanation, the frequency of losses would be significantly higher.

After ruling out the known anomaly and risk explanations, we then explore the nature of the price relevant information in earnings acceleration that is apparently missed by the market leading to the abnormal returns. We specifically examine whether earnings acceleration has implications for subsequent earnings growth and whether these implications are missed by the market. Recall that, in the PEAD context, the measure of earnings growth (which is basically earnings change from a seasonal random walk model − labeled Standardized Unexpected Earnings or SUE) has been shown to predict future earnings growth, especially one quarter ahead. We test and find that earnings acceleration has implications for earnings growth, especially two and three quarters ahead. Such prediction is incremental to the predictions of past earnings growth, which have been documented before in the context of the PEAD. We also find significant short-window three-day abnormal returns surrounding earnings announcements of these two future quarters. Significant short-window announcement returns make a risk-based explanation for the anomaly unlikely (Brown and Warner, 1980, 1985; Rangan and Sloan, 1998).

Since earnings acceleration is associated with both future returns and future earnings growth, we structure a formal efficiency test to directly associate the future returns from earnings acceleration with the implications of earnings acceleration for future earnings growth. Along the lines of Sloan (1996), we employ the Mishkin test and document that the abnormal returns are associated with the relation between earnings acceleration and future earnings growth.[3]

Having shown that the excess returns are consistent with the market missing the implications of earnings acceleration for future earnings growth, we then explore a possible information processing bias underlying the market missing these implications.[4] It is well known that most quarterly earnings announcements are accompanied by a comparison to earnings from the corresponding fiscal quarter a year ago. The abnormal returns documented in this study are consistent with investors anchoring on earnings change from four quarters ago (i.e., assuming earnings follows seasonal random walk) and ignoring intermediate earnings outcomes. If the true earnings process follows a seasonal random walk (SRW), there would be zero correlation between earnings acceleration and future earnings growth. However, the empirically observed non-zero correlations between earnings acceleration and future earnings growth (and future returns) occur when we assume that the true earnings process is non-seasonal like, for example, IMA (1,1). Thus, our finding of the market missing the implications of earnings acceleration for future earnings growth is consistent with the market adopting a SRW model (thus assuming zero correlations between earnings acceleration and future growth) when the true process is IMA (1,1).[5]

Furthermore, we analytically show that the correlations between earnings acceleration and three of the next four quarters' earnings growths monotonically decrease in the IMA (1,1) parameter, and the correlation for the other quarter is nearly constant. The IMA (1,1) parameter represents the extent of mean reversion in the earnings process. Thus, if the market is missing the above correlations, the excess returns will be larger with lower mean reversion. Consistent with this prediction, we document that earnings acceleration effect is stronger among profit firms and among firms with low earnings volatility, both of which have been shown to be associated with lower mean reversion (Brooks and Buckmaster, 1976; Dichev and Tang,

[2] While majority of our tests focus on earnings acceleration, we show that general acceleration strategies involving changes in growth of sales and profitability demonstrate similar abnormal returns.

[3] Some recent studies employing the Mishkin test framework include Chen and Shane (2014), Hui et al. (2016) and Ma and Markov (2016).

[4] Fama (1998) argues that documenting abnormal returns alone is not enough and recommends the presentation of a valid alternative model documenting information processing biases that can explain the observed results. A notable feature of our study is that we provide such an alternative.

[5] While the signs of the correlations observed between earnings acceleration and future earnings growth can be generated by a number of non-SRW processes, the IMA (1,1) assumption appears to predict the magnitudes of the correlations well and hence appears to be a reasonable approximation for the true earnings process in this specific context.

2009). Additionally, going long on high earnings acceleration firms represented by consecutive positive earnings growth quarters (which signifies low mean reversion) and going short on low earnings acceleration firms represented by positive earnings growth followed by negative earnings growth can improve the anomalous returns by nearly 45% (from 1.8% to 2.6% over a month).

Recently, there are heightened p-hacking concerns with studies documenting anomalies. Harvey et al. (2016) recommend a higher hurdle (t-statistic greater than 3.0) for any new variable purporting to explain the cross-section of returns. Earnings acceleration comfortably beats this hurdle. Green et al. (2017) document that post-2003 returns from several well-documented anomalies are insignificantly different from zero. The earnings acceleration anomaly continues to perform well even in the post-2003 period. Several previously documented anomalies do not remain significant when equal-weighted portfolios are replaced by value-weighted portfolios (Hou et al., 2017). Our results remain robust to the construction of value-weighted portfolios.

To our knowledge, this is the first study to examine the implications of earnings acceleration for future returns. Cao et al. (2011) find that annual earnings acceleration is associated with long window contemporaneous returns.[6] We make two significant departures from Cao et al. (2011) in this study. First, we focus on *future* returns rather than *contemporaneous* returns since we are interested in whether the market is efficient in incorporating the effects of earnings acceleration. Second, given the anomaly context, we focus on *quarterly* earnings growth rather than *annual* earnings growth since much of the information to the market in an annual earnings number has been pre-empted by three quarterly earnings numbers and likely is assimilated in the stock price well before the annual earnings information is released (see Lee, 1992, and Landsman and Maydew, 2002 for evidence on the speed with which accounting information is assimilated into stock prices).[7] Consequently, earnings acceleration in this study is measured as the change in earnings growth from one quarter to the next, while earnings growth is the change in earnings over the corresponding quarter a year ago.[8]

In sum, we document that abnormal returns can be earned by employing a trading strategy that goes long in high past earnings acceleration stocks and short in low past earnings acceleration stocks. The excess returns are robust to risk adjustments and other known anomalies, and are particularly relevant given the recent general disillusionment with several accounting based anomalies not being robust (Linnainmaa and Roberts, 2017; Hou et al., 2017). Additionally, we show that the anomaly is consistent with a specific information processing bias - anchoring on a SRW model for quarterly earnings. While prior literature has documented future return implications of earnings levels (Novy-Marx, 2013), earnings changes (Bernard and Thomas, 1990; Akbas et al., 2017) and earnings volatility (Cao and Narayanamoorthy, 2012), this study contributes to the literature by documenting the future return implications of earnings acceleration or the second derivative of earnings.

While we consider the abnormal returns associated with earnings acceleration a new anomaly, we acknowledge that our results can be interpreted alternatively as premium from an as yet unknown risk factor. Based on a simple dividend discount model, Fama and French (2006) demonstrate a positive relation between expected return and future profitability. Since earnings acceleration is related to future profitability, from a rational pricing perspective, earnings acceleration can alternatively be labeled a risk factor (Penman and Zhu, 2014). Regardless of the labeling, the main take-way from this study is that earnings acceleration is associated with future excess returns, and the association cannot be explained by known risk factors.

The rest of the study is organized as follows. In section 2, we present the data and basic excess return results from the acceleration-based trading strategy. We also discuss how the anomaly is distinct from previously documented anomalies and is robust to risk adjustments. In section 3, we present results on the implications of earnings acceleration for future earnings growth and short-window abnormal return tests around future earnings announcements. We also conduct formal statistical tests of the association between abnormal returns and the earnings acceleration – future earnings growth relation. In section 4, we analytically examine the relation between earnings acceleration and future earnings growth assuming the true earnings process follows IMA (1,1). In section 5, we consider alternative earnings acceleration patterns and discuss additional robustness tests. In section 6, we provide our concluding remarks.

2. Earnings acceleration and future returns

In this section, we begin with discussing our sample selection and variable construction. Next, we document abnormal returns from portfolio tests of the acceleration-based trading strategy. We also document the robustness of these returns to risk as well as to other known anomalies. Finally, we augment our portfolio test results by conducting regression tests of the anomaly.

[6] Others have used an earnings acceleration measure in their empirical tests (Aboody et al., 2004; Copeland et al., 2004; Chen and Zhang, 2007). However, they include the *forecasted* change in earnings growth in their return models, while we include the *current* (realized) change in earnings growth. Additionally, while earnings acceleration is simply a control variable in these prior studies, it is the focus of this study.

[7] A trading strategy involving annual earnings acceleration as defined in Cao et al. (2011) does not yield excess returns.

[8] There is a vast amount of literature beginning with Latané et al. (1969) that documents 4th difference in earnings to be the relevant growth measure in the context of quarterly earnings.

2.1. Data and descriptive statistics

2.1.1. Sample selection

Data used in this study is obtained from CRSP-Compustat Merged (quarterly), CRSP (daily), and I/B/E/S (detail) databases. The sample selection procedure includes all quarterly earnings announcements from CRSP-Compustat Merged database between 1972 and 2015. We delete observations if a firm has (i) more than one earnings announcement on any date, (ii) earnings announcement date within 30 days of a previous earnings announcement date or (iii) earnings announcement date either prior to or more than 180 days after the corresponding fiscal period-end, as these observations are potentially subject to data errors. We restrict the sample to NYSE, AMEX and NASDAQ firms that have stock return data in CRSP. We exclude financial and utility firms with SIC codes from 6000 to 6999 and from 4900 to 4949, as financial and utility firms were highly regulated during much of our sample period, which can result in unusual earnings-return relationships. We require that every observation has non-missing data to calculate market capitalization (SIZE), book-to-market ratio (BM), one-month market-adjusted return (VMAR) and the various earnings acceleration measures. Our final sample consists of 8,824 firms and 377,907 firm-quarter observations from 1972 to 2015. Table 1 summarizes the sample selection procedure.

2.1.2. Construction of earnings acceleration and other variables

The measurements for all the variables used in this study are summarized in Table 2. The primary variable of interest is our earnings acceleration measure, which we define as the earnings growth in quarter t minus the earnings growth in quarter t-1. Earnings growth in quarter t is calculated as the deflated change in earnings per share (EPS) from quarter t-4 to quarter t (that is, seasonally differenced EPS).[9] We consider three alternative deflators for our earnings growth measure: the absolute value of EPS in quarter t-4, the stock price at the end of quarter t-1, and the standard deviation of EPS calculated from the most recent eight quarters (including quarter t). In other words, our earnings growth measures, EGA, EGP and EGV, are scaled measures of $EPS_t - EPS_{t-4}$. In addition, we also consider sales growth and profitability growth as alternative growth measures[10]. We define sales growth as seasonally differenced sales per share (SPS), deflated by sales per share four quarters ago, and profitability growth as the seasonally differenced return-on-assets (ROA). Thus, our first definition of earnings acceleration (EAA) is calculated as:

$$EAA_{i,t} = EGA_{i,t} - EGA_{i,t-1} = \frac{EPS_{i,t} - EPS_{i,t-4}}{|EPS_{i,t-4}|} - \frac{EPS_{i,t-1} - EPS_{i,t-5}}{|EPS_{i,t-5}|}$$

Our second definition of earnings acceleration (EAP) is calculated as:

$$EAP_{i,t} = EGP_{i,t} - EGP_{i,t-1} = \frac{EPS_{i,t} - EPS_{i,t-4}}{\text{Stock Price}_{i,t-1}} - \frac{EPS_{i,t-1} - EPS_{i,t-5}}{\text{Stock Price}_{i,t-2}}$$

Table 1
Sample Selection.
This table reports the sample selection procedures. Data are firm-quarter observations from 1972 to 2015.

All Compustat-CRSP merged database firm-quarters between 1972 and 2015	1,027,392	100%
Drop observations with missing earnings announcement date	(231,338)	−23%
Drop observations with more than one earnings announcement on the same date for the same firm	(2,215)	0%
Drop observations whose current quarter earnings announcement date is before or more than 180 days after current quarter fiscal period end date	(1,483)	0%
Drop if current earnings announcement is less than 30 days away from the previous earnings announcement	(3,976)	0%
Keep NYSE, AMEX or NASDAQ firms	(177,462)	−17%
Drop firms with SIC codes between 6000 and 6999 or between 4900 and 4949	(141,008)	−14%
Keep observations with nonmissing CRSP daily price at the earnings announcement date	(8,218)	−1%
Keep domestic common stocks	(38,998)	−4%
Drop observations with missing SIZE or BM	(4,036)	0%
Drop observations with all five acceleration measures (i.e., EAA, EAP, EAV, SA and PA) missing	(40,224)	−4%
Drop observations with missing VMAR	(527)	0%
Total	377,907	37%

[9] Following Cao et al. (2011) and Chan et al. (2003), we define earnings acceleration on a per share basis to account for the effects of mergers and acquisitions, as well as to strip out any predictability due to changes in the scale of the firm's operations.
[10] Chan et al. (2003) suggest using sales growth as an additional growth measure due to problems with negative base-period earnings. We include profitability growth because it is similar to the measure used by Cao et al. (2011).

Table 2
Variable Definitions.
This table summarizes variable definitions.

Variables	Descriptions
VMAR	Value-weighted market-adjusted buy-and-hold return during the one-month window, defined as the raw return (two days through 30 days after quarter t earnings announcement date) adjusted for the same period CRSP value-weighted index return
VMARQ	Value-weighted market-adjusted buy-and-hold return during the quarter-long window, defined as the raw return (two days after quarter t earnings announcement date through one day after quarter t+1 earnings announcement date) adjusted for the same period CRSP value-weighted index return
EMAR	Equal-weighted market-adjusted buy-and-hold return during the one-month window following earnings announcement date
SAR	Size-adjusted buy-and-hold return during the one-month window following earnings announcement date
FF3	Fama-French three-factor-adjusted buy-and-hold return during the one-month window following earnings announcement date
FFM	Fama-French three-factor and momentum-adjusted buy-and-hold return during the one-month window following earnings announcement date
FF5	Fama-French five-factor-adjusted buy-and-hold return during the one-month window following earnings announcement date
EGA	Earnings growth (deflated by absolute value of earnings), defined as quarter t's earnings per share (EPS) minus quarter t-4's EPS, scaled by the absolute value of quarter t-4's EPS; where EPS is calculated as income before extraordinary items (IBQ), divided by shares outstanding (CSHOQ). Shares are adjusted for stock splits and stock dividends.
EGP	Earnings growth (deflated by price), defined as quarter t's EPS minus quarter t-4's EPS, scaled by the stock price at the end of quarter t-1
EGV	Earnings growth (deflated by standard deviation of earnings), defined as quarter t's EPS minus quarter t-4's EPS, scaled by the standard deviation of EPS in the most recent 8 quarters (including quarter t)
SG	Sales growth, defined as quarter t's sales per share (SPS) minus quarter t-4's SPS, scaled by quarter t-4's SPS; where quarter t's SPS is calculated as net sales (SALEQ), divided by shares outstanding (CSHOQ). Shares are adjusted for stock splits and stock dividends.
PG	Profitability growth, defined as quarter t's return-on-assets (ROA) minus quarter t-4's ROA; where ROA is defined as operating income after depreciation (OIADPQ) per share at quarter t, divided by total assets (ATQ) per share at quarter t-1. Shares are adjusted for stock splits and stock dividends.
EAA	Earnings acceleration (absolute value of earnings deflated), defined as quarter t's EGA minus quarter t-1's EGA
EAP	Earnings acceleration (price deflated), defined as quarter t's EGP minus quarter t-1's EGP
EAV	Earnings acceleration (standard deviation of earnings deflated), defined as quarter t's EGV minus quarter t-1's EGV
SA	Sales acceleration, defined as quarter t's SG minus quarter t-1's SG
PA	Profitability acceleration, defined as quarter t's PG minus quarter t-1's PG
MSCORE	Mispricing factor, from Yu Yuan's website (http://www.saif.sjtu.edu.cn/facultylist/yyuan/)
TREND	Trend in quarterly gross profitability, measured as b1 from estimating the following trend regression each quarter: GPQ = a0 + b1*t + b2*D1 + b3*D2 + b4*D3 + ε; where GPQ is calculated as sales (SALEQ) minus cost of goods sold (COGSQ), divided by total assets (ATQ)
SIZE	Market capitalization, defined as market price at earnings announcement date multiply by the total number of shares outstanding
BM	Book-to-market ratio, defined as the book value of equity at the end of quarter t divided by the market capitalization at earnings announcement date
PASTRET	Past return, defined as the value-weighted market-adjusted stock return during the [-180,-2] window before quarter t earnings announcement date
GP	Gross profitability, defined as quarter t's SALEQ minus COGSQ, divided by ATQ
ACC	Accruals, defined as quarter t's (ΔACTQ - ΔCHEQ - ΔLCTQ + ΔDLCQ + ΔTXPQ)/Average ATQ, where ACTQ, CHEQ, LCTQ, DLCQ, TXPQ represent current assets, cash and short-term investments, current liabilities, debt in current liabilities and income tax payable, respectively
VOL	Earnings volatility, defined as standard deviation of EPS in the most recent 8 quarters (including quarter t)
AG1	Asset growth (definition 1), defined as quarter t's total assets per share minus quarter t-1's total assets per share, divided by quarter t-1's total assets per share
AG2	Asset growth (definition 2), defined as quarter t's total assets per share minus quarter t-4's total assets per share, divided by quarter t-4's total assets per share
VMAR3	Value-weighted market-adjusted buy-and-hold return during the earnings announcement window, defined as the raw return (one day before through one day after quarter t earnings announcement date) adjusted for the same period CRSP value-weighted index return

Our third definition of earnings acceleration (EAV) is calculated as:

$$EAV_{i,t} = EGV_{i,t} - EGV_{i,t-1} = \frac{EPS_{i,t} - EPS_{i,t-4}}{SDEPS_{i,t}} - \frac{EPS_{i,t-1} - EPS_{i,t-5}}{SDEPS_{i,t-1}}$$

Our definition of sales acceleration (SA) is calculated as:

$$SA_{i,t} = SG_{i,t} - SG_{i,t-1} = \frac{SPS_{i,t} - SPS_{i,t-4}}{SPS_{i,t-4}} - \frac{SPS_{i,t-1} - SPS_{i,t-5}}{SPS_{i,t-5}}$$

Our definition of profitability acceleration (PA) is calculated as:

$$PA_{i,t} = PG_{i,t} - PG_{i,t-1} = \left(ROA_{i,t} - ROA_{i,t-4}\right) - \left(ROA_{i,t-1} - ROA_{i,t-5}\right)$$

Please cite this article as: He, S., Narayanamoorthy, G., Earnings acceleration and stock returns, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101238

While our basic portfolio tests employ all five acceleration measures, we use EAP as our primary measure of focus in subsequent tests for two reasons. First, earnings is the most widely accepted optimal measure of firm performance. Second, the use of price as deflator is consistent with the broad capital markets literature in accounting.

To mitigate the impact of outliers, we follow prior research (see, for example, Rangan and Sloan, 1998; Livnat and Mendenhall, 2006) and transform our earnings acceleration measures into decile ranks. The decile cutoffs are based on the distribution of the previous fiscal quarter's earnings accelerations. The decile ranks are initially numbered 0 through 9. We then convert the numbers to scaled ranks by dividing by 9 and subtracting 0.5. The resulting scaled ranks vary from −0.5 to +0.5 with a mean of zero and a range of one. The range of one implies that the coefficient on earnings acceleration in a return regression represents the abnormal return from a zero investment strategy of going long on the highest earnings acceleration decile and short on the lowest earnings acceleration decile. This choice of range facilitates a comparison of the economic magnitudes of our main results to prior research.

The primary abnormal return measures in our study are calculated over two windows: (a) a window beginning two days after quarter t's earnings announcement date and ending on day 30, and (b) a window beginning two days after quarter t's earnings announcement date and ending one day after quarter t+1's earnings announcement date. We use value-weighted market-adjusted return as our measure for abnormal returns, and calculate the return as the difference between a firm's buy-and-hold raw return and the same period CRSP value-weighted index return.[11]

2.1.3. *Descriptive statistics*

Table 3 presents descriptive statistics for the sample. In Panel A, the mean and median of all five earnings acceleration measures are either negative or zero, indicating that the average firm's growth rate decreased over the time-period used in our study. In Panel B, we report Spearman and Pearson correlations among variables. Both one-month and quarter-long abnormal returns are positively correlated with all five earnings acceleration measures. The Spearman (Pearson) correlation between one-month value-weighted market-adjusted return (VMAR) and EAA, EAP, EAV, SA and PA are 0.037 (0.013), 0.043 (0.018), 0.044 (0.039), 0.034 (0.022) and 0.045 (0.029), respectively; which indicates a possible positive association between earnings acceleration and future returns. We also note that the earnings acceleration variables are negatively correlated with the profitability trend (TREND) variable, suggesting that our earnings acceleration measures represent a phenomenon different from the profitability trend phenomenon documented in Akbas et al. (2017).[12]

2.2. *Basic empirical results*

In Table 4, we present the results for both the one-month and quarter-long market-adjusted returns sorted into acceleration deciles for the five measures of acceleration. In Panel A, we report the results for equal-weighted average portfolio returns. The month-long VMAR for the bottom decile on EAP is −0.2% while the VMAR for the topmost decile is 1.6%. This represents a hedge portfolio return of 1.8% over one month, which in annualized terms is an excess return exceeding 23%. Over the quarter-long window, the corresponding hedge return is 3.4%. The hedge portfolio returns for the other four measures of acceleration over both return windows are comparable. Additionally, moving from the bottom decile to the top decile, the stock returns are monotonically increasing, showing that the anomaly gradually increases in acceleration decile and is not concentrated in a particular decile. In Fig. 1, we show the evolution of the cumulative abnormal return over the month-long (day 2 to day 30) window for the top and bottom decile of earnings acceleration. Decile one has a small negative return in the immediate aftermath of the earnings announcement and then remains at roughly that level for the entire month. Decile ten, on the other hand, increases virtually monotonically to reach 1.6% at day 30. Recent research has documented that several anomalies vanish when equal-weighted portfolios are replaced by value-weighted portfolios (Hou et al., 2017). In Panel B, we report the results for value-weighted average portfolio returns, and we find that the returns remain robust to this portfolio construction. The value-weighted portfolio for EAP, our primary acceleration variable, yields a hedge return of 1.5% over a month compared to 1.8% for the equal-weighted portfolio. The table also presents results when other acceleration variables are used. The other four acceleration measures (EAA, EAV, SA and PA) all yield consistently positive abnormal returns.

In Table 5, we present the results for the robustness of the anomaly to alternative risk adjustments. Columns one through five present returns for equal-weighted portfolios and columns six through ten provide the results for value-weighted portfolios.[13] Recall that our base results already adjust for value-weighted market index returns. In column one, we present stock returns adjusted for equal-weighted market index returns (EMAR). The excess returns again show a monotonically

[11] If a stock is delisted subsequent to portfolio formation, we compute the remaining return using the CRSP delisting return if it is available. Thereafter we reinvest any remaining proceeds in the market portfolio until the end of the holding period.

[12] Notwithstanding the negative correlation, our earnings acceleration measure is also conceptually different from the trend variable in Akbas et al. (2017). In Akbas et al. (2017), the trend in profitability is defined as the trend coefficient in an earnings level regression, meaning that the trend variable is an average of past quarter over quarter growth rates. In contrast, our earnings acceleration measure represents the change in the past quarter over quarter growth rates.

[13] While we present the results for one earnings acceleration measure (EAP) in the month-long return window, the results for this measure in the quarter-long window are similarly significant. Additionally, the results for the other four acceleration measures (EAA, EAV, SA and PA) in both return windows are similar to the results for EAP.

Table 3
Descriptive Statistics.
This table provides descriptive statistics for our sample. See Table 2 for variable definitions. Panel A reports the summary statistics. Panel B reports correlations among variables. Spearman (Pearson) correlations are presented above (below) the diagonal. Correlations that are significant at the 1% significance level are marked in bold.

Panel A: Summary statistics

	N	Mean	Std. Dev.	Q1	Median	Q3

Table 4
Portfolios Formed Based on Acceleration Measures.
This table reports the average market-adjusted returns for portfolios formed based on acceleration deciles. See Table 2 for variable definitions. t-statistics are reported in parentheses, and are calculated based on the time-series of the portfolio market-adjusted stock returns.

increasing trend across the EAP deciles and the hedge portfolio return is again 1.8%. In column two, we present the results of the EAP strategy using size-adjusted returns and again obtain a hedge portfolio return of 1.8%. In columns three and four, we employ returns that are adjusted by the typical Fama French (FF) factors. Column three presents the results with the traditional three factor model and column four uses the Fama French three factor plus Momentum adjustment. Recently, Fama and French (2015) have developed and tested a five-factor model that extends their original three-factor model with investment and profitability factors. They argue that this augmented model explains a number of well-documented anomalies. In column five, we test the robustness of the earnings acceleration strategy to this augmented risk model and show that the excess hedge portfolio return remains significant over the month long window. Columns six through ten present qualitatively similar results for value-weighted portfolio returns and provide confidence in the robustness of the results to various risk adjustments. In all the remaining tests, we continue to employ the VMAR measure for excess returns.

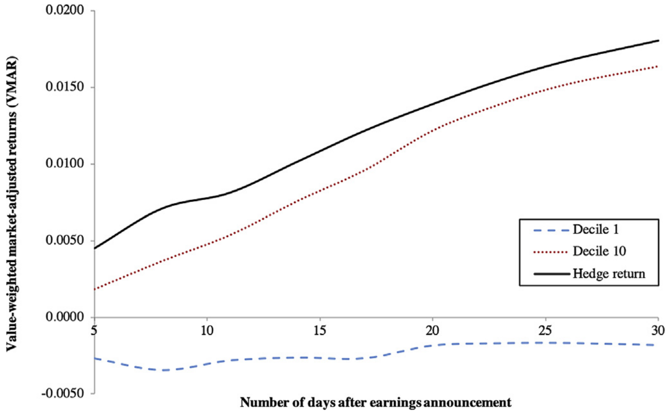

Fig. 1. Earnings Acceleration Strategy over Different Horizons.
This figure depicts the difference in value-weighted market-adjusted returns (VMAR) between top and bottom earnings acceleration (EAP) deciles over different time horizons (after earnings announcement). The x-axis represents the number of days after the earnings announcement date. The y-axis represents the VMAR for the top and bottom EAP deciles as well as their difference averaged over 176 fiscal quarters from 1972 till 2015. See Table 2 for variable definitions.

Table 5
Portfolios Formed Based on Earnings Acceleration: Alternative Risk Adjustments.
This table reports the average one-month risk-adjusted returns for portfolios formed based on EAP deciles. See Table 2 for variable definitions. t-statistics are reported in parentheses, and are calculated based on the time-series of the portfolio risk-adjusted stock returns.

In Table 6, we examine the robustness of the earnings acceleration strategy to other well-documented anomalies. Stambaugh and Yuan (2017) create a comprehensive mispricing measure — M-Score that incorporates several well-documented anomalies. In Panel A, we examine the robustness of the earnings acceleration strategy hedge portfolio excess returns to this M-Score measure. We follow Liu et al. (2017) in constructing portfolios independently sorted on both the M-Score measure as well as our variable of interest, namely earnings acceleration. As we move from column one to column five, we move from the lowest quintile to the highest quintile of earnings acceleration. Similarly, when we move from row one to row five, we move from the lowest M-Score (which represents underpricing) to the highest M-score (which represents overpricing). The last column depicts the returns from a hedge portfolio strategy of going long on highest quintile of earnings acceleration and short on the lowest quintile of earnings acceleration. The trading strategy yields consistently positive returns across all rows showing the robustness of the strategy to other well documented anomalies captured in M-

Table 6
Portfolios Formed Based on Earnings Acceleration and Other Anomaly Variables.
This table reports the average one-month market-adjusted returns for equal-weighted portfolios formed based on EAP deciles and other anomaly variables (using independent sorting). See Table 2 for variable definitions. t-statistics are reported in parentheses, and are calculated based on the time-series of the portfolio market-adjusted stock returns.

Score.[14] More importantly, the lowest excess return is still economically large at 1.2% over the month long window. The returns to the M-score strategy, depicted along the last row, are typically lower than the magnitude of the returns for the earnings acceleration strategy. Additionally, they do not remain consistently significant across all the earnings acceleration quintiles.

In Panel B, we follow the same methodology as Panel A, but examine the joint returns from the earnings acceleration and post-earnings announcement drift (PEAD) strategies. The key variable used in traditional PEAD studies is Standardized Unexpected Earnings (SUE). The "Unexpected" earnings are the surprise from a seasonal random walk model for earnings. Thus, they are identical to the seasonal growth in earnings, which is the growth measure we use to compute earnings acceleration. As such, we use the variable EGP to represent the same SUE variable that has been employed in the PEAD literature. Again, we

[14] The same pattern is observed when we use deciles instead of quintiles.

obtain significant excess returns to a strategy of going long in the highest EAP quintile and short in the lowest EAP quintile across all rows (as shown in the last column) and the lowest hedge return across the rows is 1.1%. In contrast, the PEAD strategy does not yield significant results uniformly across all EAP quintiles. Akbas et al. (2017) have recently documented a profitability trend anomaly that can potentially overlap with the earnings acceleration anomaly presented in this study. A direct comparison of the two anomalies is presented in Panel C. Once again, the earnings acceleration strategy tends to produce much higher excess returns than the profitability trend anomaly. More importantly, the acceleration anomaly is present across all profitability trend partitions, while the profitability trend anomaly appears to be significantly smaller in several of the earnings acceleration partitions.[15]

In addition to the hedge portfolio return tests, a typically more conservative test of the anomaly entails a regression analysis across all deciles. Besides including data from all deciles, another advantage of the regression approach is the ability to control for several risk factors and anomalies simultaneously. In Table 7, we present regression analysis of excess returns from the earnings acceleration strategy after including all the controls. For columns one through three, the dependent variable is the month-long excess return and for columns four through six, it is the quarter-long excess return. The main regression model estimated is:

$$\begin{aligned}\mathrm{VMAR(Q)}_{i,t} = \alpha_0 + \alpha_1 \mathrm{EGP}_{i,t} + \alpha_2 \mathrm{EAP}_{i,t} + \alpha_3 \mathrm{SIZE}_{i,t} + \alpha_4 \mathrm{TREND}_{i,t} + \alpha_5 \mathrm{BM}_{i,t} + \alpha_6 \mathrm{PASTRET}_{i,t} + \alpha_7 \mathrm{GP}_{i,t} + \alpha_8 \mathrm{ACC}_{i,t} \\ + \alpha_9 \mathrm{VOL}_{i,t} + \alpha_{10} \mathrm{AG}_{i,t} + \varepsilon_{i,t}\end{aligned} \tag{1}$$

where EAP is earnings acceleration, defined as quarter t earnings growth minus quarter t-1 earnings growth, and earnings growth is the seasonal change in EPS scaled by the stock price at the end of quarter t-1 (see Table 2).

The standard errors employed are from Fama-Macbeth regressions (with Newey-West correction with six lags) and hence are controlled for cross-sectional and serial correlation in the panel data. Model one includes controls for the PEAD strategy and size and model two includes additional controls for the profitability trend, book-to-market, past returns, profitability, accruals, earnings volatility and asset growth. In the discussion, we focus on the results from model two. The regression coefficient on EAP, our earnings acceleration variable, is 0.016. Recall that the EAP decile rank variable has been scaled to have

Table 7
Earnings Acceleration and Stock Returns: Regression Analysis.
This table reports the regression results testing the relation between earnings acceleration and stock returns. See Table 2 for variable definitions. [15] We get similar results using Fama-French three- and five-factor adjusted returns instead of VMAR for all three panels A, B and C.

a range of one and a mean of zero. Thus, the coefficient of 0.016 can be interpreted as the return (1.6%) from a hedge portfolio that entails going long in the highest decile of earnings acceleration and short on the lowest decile. In column five, the corresponding incremental return is 2.3%. These returns are comparable in magnitude to the PEAD anomaly, which had returns of 1.2% over the first month and 3.8% over a quarter. Book-to-market and gross profitability have incremental returns of 1.4% (2.5%) and 1.1% (1.7%) over the next month (quarter), respectively. In contrast, the profit trend anomaly only yields incremental returns of 0.5% over the month and 1.3% over the quarter.[16]

3. Earnings acceleration and future earnings growth

So far, we have demonstrated that earnings acceleration can predict future stock returns and that these returns are robust to adjustments for risk and other known anomalies. We now explore the nature of the information contained in earnings acceleration. We examine whether earnings acceleration has incremental predictive ability for future earnings growth and whether the future abnormal return from the earnings acceleration strategy documented in section 2 is associated with this predictive ability.[17] If so, the abnormal return we document likely manifests because investors do not consider fully the implications of earnings acceleration for future earnings growth.

3.1. Implications of earnings acceleration for future earnings growth

We estimate a regression of future earnings growth on past earnings acceleration. Since past earnings growth has been shown to predict future earnings growth (in the PEAD context), we also control for past earnings growth to document that the implications of earnings acceleration are incremental.

$$\mathrm{EGP}_{t+k} = \alpha + \beta \mathrm{EAP}_t + \gamma \mathrm{EGP}_t + \varepsilon_{t+k} \tag{2}$$

Here k takes on the values 1, 2 and 3 meaning that EGP_{t+k} represents the seasonal earnings growth one, two and three quarters in the future.

Table 8 reports the regression results testing the relation between earnings acceleration and the earnings growth for each of the three subsequent quarters. Columns one, four and seven represent the basic relation between earnings acceleration and future earnings growth one, two and three quarters, respectively, in the future. While the coefficient for one quarter ahead growth is negative, the coefficients for the two subsequent quarters (i.e., 0.046 and 0.237) are significantly positive.[18] The other columns examine the effect of earnings acceleration for future earnings growth after including various controls for a wide range of potential explanatory variables for earnings growth. These control variables are defined in Table 2. With controls, the coefficients on EAP for every subsequent quarter are positive, though they are consistently stronger for earnings growth two and three quarters into the future than for one quarter into the future. In columns five and eight, the coefficients are significantly positive at 0.056 and 0.248, respectively, suggesting that earnings acceleration is a significant predictor of future two- and three-quarters-ahead earnings growth. Economically, moving from the bottom decile to the top decile of scaled earnings acceleration leads to a nearly 25% incremental change in the decile of earnings growth three quarters hence. For comparison, the EGP coefficient, that is relevant in the PEAD context, is 32% for one quarter ahead earnings growth (column two), and is actually negative (−4.5% in column eight) for three quarters ahead earnings growth.

3.2. Short-window returns around future earnings announcement dates

While our primary results employ one-month and quarter-long abnormal returns and are robust to controlling for a litany of risk factors, a further intuitive test involves shorter-window returns, which are typically less susceptible to risk considerations (Bernard and Thomas, 1990; Sloan, 1996). Specifically, since we wish to assess whether the earnings acceleration anomaly is attributable to the market missing, at least partially, the implications of earnings acceleration for earnings growth two and three quarters in the future, we examine whether abnormal returns occur in short windows around earnings announcements two and three quarters ahead.

Table 9 reports the regression results testing the relation between earnings acceleration and the three-day abnormal return surrounding each of the three subsequent earnings announcements. The coefficient on EAP is positive and significant in all columns (ranging in magnitude from 0.2% to 0.8%). The short-window excess returns are largest around the third subsequent quarter's earnings announcement (ranging from 0.7% to 0.8% in columns seven through nine). These magnitudes are comparable to or larger than historically reported three-day returns in the PEAD context. Our finding that earnings acceleration is positively associated with three-day returns around all three subsequent earnings announcements strongly indicates that investors do not appear to incorporate fully the implications of earnings acceleration for subsequent earnings in

[16] These results remain robust to estimating Fama-MacBeth regressions based on market-value-weighted least squares method as in Green et al. (2017).
[17] Such a test is analogous to the PEAD context, where current earnings growth from a seasonal random walk model had implications for future earnings growth and these implications have been shown to be associated with PEAD (see Bernard and Thomas, 1990; Rangan and Sloan, 1998, among others).
[18] When EGP is excluded, the coefficient on EAP is significantly positive and economically large for one quarter ahead as well.

a timely fashion. Although a significant portion of the mispricing is corrected in the one-month following an earnings announcement, some of the correction only takes place when future quarterly earnings are announced (especially two and three future fiscal quarters).

3.3. The association between earnings acceleration's implications for future earnings growth and for future stock returns

Having documented that earnings acceleration has implications for both earnings growth up to three quarters in the future and for three-day returns surrounding each of the three subsequent earnings announcements, we then conduct a formal statistical analysis of market efficiency, i.e., the Mishkin test. In earnings-based anomaly literature, several prior studies conduct the Mishkin test to examine whether the signs and magnitudes of abnormal stock returns reflect the market's understanding of the earnings process.[19] A primary advantage of the Mishkin test is that the test of market efficiency remains valid regardless of what other correlated (omitted) variables help to predict earnings (Lewellen, 2010). In our Mishkin test, we simultaneously estimate two equations (one for future abnormal returns [VMAR] and one for future earnings growth [EGP_{t+k}]). EGP_t is also included as an independent variable in both the equations to ensure that the effect documented is incremental to the previously known effect of earnings growth on future earnings growth and future stock return. Simultaneous estimation establishes whether the relation between future growth (EGP_{t+k}) and past acceleration (EAP_t) implicit in future abnormal returns (VMAR) is the same as the directly observable relation between future earnings growth and past earnings acceleration.

If the market correctly understands the implications of the earnings process depicted in Eq. (2), any price response subsequent to the earnings announcement should not be related to past earnings acceleration and only be related to the earnings growth surprise ε_{t+k}. Specifically, assuming the price response to ε_{t+k} over the month subsequent to the current earnings announcement is linear, we have

[19] See, for example, Sloan (1996), Dechow and Sloan (1997), Rangan and Sloan (1998), Collins and Hribar (2000), Narayanamoorthy (2006), Cao and Narayanamoorthy (2012), Chen and Shane (2014), Hui et al. (2016) and Ma and Markov (2016).

Table 9
Earnings Acceleration and Future Three-Day Abnormal Returns around Earnings Announcements.
This table reports the regression results testing the relation between earnings acceleration and future three-day abnormal returns around earnings announcements. See Table 2 for variable definitions. Standard errors are from a Fama-MacBeth estimation with Newey-West correction for up to six lags. t-statistics are reported in parentheses. ***, **, * indicate significantly different from zero at the 1%, 5%, 10% level, respectively.

$$VMAR_{t+1} = k_0 + k_1\varepsilon_{t+k} + \mu_{t+1} \tag{3}$$

If the market is efficient in incorporating the effect of earnings acceleration, it will only respond to the actual innovation (or noise) after controlling for acceleration. In other words, if the market correctly infers the relation in Eq. (2), ε_{t+k} in Eq. (3) will be the same as ε_{t+k} in Eq. (2). Substituting ε_{t+k} with $EGP_{t+k} - \alpha - \beta EAP_t - \gamma EGP_t$ from Eq. (2), we then get

$$VMAR_{t+1} = k_0 + k_1(EGP_{t+k} - \alpha - \beta EAP_t - \gamma EGP_t) + \mu_{t+1}$$

which, on rearranging, yields

$$VMAR_{t+1} = (k_0 - k_1\alpha^*) + k_1 EGP_{t+k} - k_1\beta^* EAP_t - k_1\gamma^* EGP_t + \mu_{t+1} \tag{4}$$

In Eq. (2), β is the actual coefficient on our variable of interest while in Eq. (4), β^* is the coefficient inferred from the market's expectation of EGP_{t+k}.[20] The restriction $\beta = \beta^*$ yields a likelihood ratio statistic that has a chi-square distribution with one degree of freedom. If $\beta^* = 0$, then we conclude that the market appears to completely ignore the implications of earnings acceleration for future earnings growth. If $\beta^* = \beta$, then the market appears to understand the implications of earnings acceleration perfectly. If $0 < \beta^* < \beta$, then the market partially understands the earnings acceleration. If $\beta^* < 0$, then the market not only underestimates the implications of earnings acceleration, but also prices stocks as if they expect current earnings acceleration to have negative implications for future earnings growth.

We present the results of the Mishkin Test in Table 10. Panel A presents the results from jointly estimating the one-quarter-ahead earnings forecasting equation and the pricing equation. While the coefficient (β) on the actual correlation between earnings acceleration and one-quarter-ahead earnings growth is −0.031, the coefficient (β^*) on market's assessment (based on one month excess returns) of the effect is −0.564. Panel B presents the results from jointly estimating the two-quarters-

[20] Standard OLS does not readily provide direct estimates and associated standard errors for β^*. The Mishkin framework, in contrast, extracts the underlying parameter estimates by using non-linear least squares estimation and is asymptotically equivalent to OLS. Thus, the Mishkin approach allows us to directly estimate and test hypotheses relating to the implications of earnings acceleration for future stock returns (Dechow et al., 2011).

Table 10
Test of Stock Market Efficiency for the Earnings Acceleration Effect.
This table reports the regression results from nonlinear generalized least squares estimation of the following two equations.
$EGP_{t+k} = \alpha + \beta EAP_t + \gamma EGP_t + \varepsilon_{t+k}$
$VMAR_{t+1} = (k_0 - k_1\alpha^*) + k_1 EGP_{t+k} - k_1\beta^* EAP_t - k_1\gamma^* EGP_t + \mu_{t+1}$
See Table 2 for variable definitions. The likelihood ratio statistic is distributed asymptotically as χ^2 with 1 degree of freedom.

ahead earnings forecasting equation and the pricing equation. While β is 0.039, indicating a positive actual association between earnings acceleration and two-quarters-ahead earnings growth, β^* is −0.5, suggesting market's negative assessment of the effect of earnings acceleration on future earnings growth. Panel C presents the results from jointly estimating the three-quarters-ahead earnings forecasting equation and the pricing equation. Estimated β of 0.238 and β^* of −0.331 suggest that while there is a significant positive association between earnings acceleration and three-quarters-ahead earnings, the market's assessment of the association between the two is incrementally negative. In all three panels, the likelihood ratio test reject that $\beta = \beta^*$, indicating that market underestimates the implication of earnings acceleration for future one-, two- and three-quarters-ahead earnings. In particular, we provide unique evidence that the market appears to not only underestimate the magnitude of the effect of earnings acceleration on two- and three-quarters-ahead earnings growth, but assumes it is incrementally negative.[21]

4. Why do investors miss the implications of earnings acceleration?

Our results in Section 3 confirm that the post-earnings acceleration returns are consistent with investors not understanding fully some of the implications of earnings acceleration for future earnings growth. In this section, we explore whether the missing of these implications is consistent with investors assuming a particular time series process for quarterly earnings when the underlying model is different.

Earnings has long been modeled in accounting research as arising either from a random walk plus noise process (Beaver et al., 1980) or as comprising of “permanent” and “transitory” components (Ali and Zarowin, 1992). Econometrically, both of these characterizations are captured by an IMA (1,1) model (Kothari, 2001). While this model assumption has primarily been applied to annual earnings, Narayanamoorthy (2006) employs it for quarterly earnings to represent a non-seasonal random

[21] β^*_k being negative for k = 1, 2 and 3 is similar to the results obtained in prior studies employing the Mishkin test (see, for example, Rangan and Sloan [1998]). If investors completely ignored the implications of earnings acceleration for future earnings growth, then β^*_k would be exactly zero. Thus, the negative values indicate that investors not only ignore the earnings acceleration implications, but also price stocks as if they expect earnings acceleration to have negative implications for future earnings.

walk process.[22] Here, we exploit the same IMA (1,1) model assumption and examine its implications for the relation between earnings acceleration and future earnings growth.

Let earnings follow a simple IMA (1,1) process with parameter $\theta \neq 0$. θ is a measure of the extent of mean reversion in earnings changes. The higher the θ, the higher the extent of mean reversion. If X_t is the earnings at time t, then the IMA (1,1) process characterizing X_t is:

$$X_t = X_{t-1} + \varepsilon_t - \theta\varepsilon_{t-1}$$

If we seasonally difference this series,

$$\begin{aligned}\Delta_4 X_t &= X_t - X_{t-4} = (X_t - X_{t-1}) + (X_{t-1} - X_{t-2}) + (X_{t-2} - X_{t-3}) + (X_{t-3} - X_{t-4}) \\ &= \varepsilon_t - \theta\varepsilon_{t-1} + \varepsilon_{t-1} - \theta\varepsilon_{t-2} + \varepsilon_{t-2} - \theta\varepsilon_{t-3} + \varepsilon_{t-3} - \theta\varepsilon_{t-4}\end{aligned}$$

$$\Delta_4 X_{t-1} = \varepsilon_{t-1} - \theta\varepsilon_{t-2} + \varepsilon_{t-2} - \theta\varepsilon_{t-3} + \varepsilon_{t-3} - \theta\varepsilon_{t-4} + \varepsilon_{t-4} - \theta\varepsilon_{t-5}$$

Then, earnings acceleration is:

$$EA_t = \Delta_4 X_t - \Delta_4 X_{t-1} = \varepsilon_t - \theta\varepsilon_{t-1} - \varepsilon_{t-4} + \theta\varepsilon_{t-5}$$

We are interested in the predictability of EA_t for $\Delta_4 X_{t+1}$, $\Delta_4 X_{t+2}$, $\Delta_4 X_{t+3}$ and $\Delta_4 X_{t+4}$. Thus,

$$\Delta_4 X_{t+1} = \varepsilon_{t+1} + (1-\theta)\varepsilon_t + (1-\theta)\varepsilon_{t-1} + (1-\theta)\varepsilon_{t-2} - \theta\varepsilon_{t-3}$$

$$\delta_{t+1} = \mathrm{Corr}(EA_t, \Delta_4 X_{t+1}) = \frac{(1-\theta)^2}{\sqrt{2(1+\theta^2)}\sqrt{1+3(1-\theta)^2+\theta^2}}$$

$$\Delta_4 X_{t+2} = \varepsilon_{t+2} + (1-\theta)\varepsilon_{t+1} + (1-\theta)\varepsilon_t + (1-\theta)\varepsilon_{t-1} - \theta\varepsilon_{t-2}$$

$$\delta_{t+2} = \mathrm{Corr}(EA_t, \Delta_4 X_{t+2}) = \frac{(1-\theta)^2}{\sqrt{2(1+\theta^2)}\sqrt{1+3(1-\theta)^2+\theta^2}}$$

$$\Delta_4 X_{t+3} = \varepsilon_{t+3} + (1-\theta)\varepsilon_{t+2} + (1-\theta)\varepsilon_{t+1} + (1-\theta)\varepsilon_t - \theta\varepsilon_{t-1}$$

$$\delta_{t+3} = \mathrm{Corr}(EA_t, \Delta_4 X_{t+3}) = \frac{\theta + (\theta-1)^2}{\sqrt{2(1+\theta^2)}\sqrt{1+3(1-\theta)^2+\theta^2}}$$

$$\Delta_4 X_{t+4} = \varepsilon_{t+4} + (1-\theta)\varepsilon_{t+3} + (1-\theta)\varepsilon_{t+2} + (1-\theta)\varepsilon_{t+1} - \theta\varepsilon_t$$

$$\delta_{t+4} = \mathrm{Corr}(EA_t, \Delta_4 X_{t+4}) = \frac{-\theta}{\sqrt{2(1+\theta^2)}\sqrt{1+3(1-\theta)^2+\theta^2}}$$

Using a representative θ value of 0.5, the correlation values are 0.112, 0.112, 0.335 and −0.224, respectively.[23] In other words, the model shows that earnings acceleration has small positive implications for earnings growth one and two quarters ahead and a much larger positive effect three quarters ahead. The implications for four quarters-ahead earnings growth are negative. Earnings acceleration's correlation with earnings growth one, two and three quarters—ahead is driven by the presence of two common error terms: ε_t and ε_{t-1}. While both the error terms reinforce each other in their implication for earnings growth three quarters ahead, they act in opposite directions in determining the correlation with earnings growth one and two quarters ahead.

[22] Several prior studies model quarterly earnings with seasonal differencing (e.g., Brown and Rozeff, 1979; Griffin, 1977; Watts, 1975; Foster, 1977). We do not employ these models here for two reasons. First, these models are shown to have limited out of sample prediction performance. Second, while quarterly earnings are shown to have both seasonal and non-seasonal characteristics, we specifically explore the theory that the market misprices the latter. Hence we need a model without seasonal differencing. We note that several other non-seasonal models like, for example, AR (1) [see Brown and Han (2000)] would yield results similar to IMA (1,1). In other words, it is not necessary for the earnings process to be IMA (1,1) for our theory of the market seasonally differencing a non-seasonal process to hold. That said, IMA (1,1) represents a wide range of economic data including earnings well (Brown, 1993) and is more readily tractable analytically.

[23] In comparison to the calculated values of the model predictions depicted above, the actual observed correlations appear to be reasonably close at 0.150, 0.132, 0.225 and −0.115, respectively. Note that the coefficient on EAP in Table 8 will be different from these correlations since the multivariate regression tests in Table 8 include controls for EGP while the model here does not.

In contrast to IMA (1,1), if the true process were a seasonal random walk (SRW) model, earnings acceleration will be $\varepsilon_t - \varepsilon_{t-1}$ and the future earnings growths would be $\varepsilon_{t+1}, \varepsilon_{t+2}, \varepsilon_{t+3}$and ε_{t+4}, respectively. In such a case, the correlations between earnings acceleration and future earnings growth would be zero. Thus, if the market uses a naïve SRW model to form earnings expectations, it assumes zero correlation between earnings acceleration and future earnings growth. Consequently, it will miss the implications (correlations) of current earnings acceleration for future earnings growth that are a result of true earnings being a process like IMA (1,1) (which appears to have empirical validity − see footnote 23).

Representing the true earnings as IMA (1,1) with mean reversion parameter, θ, allows for cross-sectional tests of the earnings acceleration effect with variation in mean reversion. In Appendix, we depict the sensitivities of the correlations between earnings acceleration and future earnings growth to θ. We find that three of the four correlations monotonically decrease in θ and the fourth correlation is almost unchanged in θ. If the market were missing the correlations between earnings acceleration and future earnings growth due to a fixation on the SRW model, we will observe greater returns when the correlations are algebraically larger, that is, when the mean reversion parameter is lower.

To empirically test this prediction, we examine the relation between earnings acceleration and future abnormal returns conditional on two measures that have been previously shown to be associated with mean reversion in earnings: losses and earnings volatility. Specifically, Brooks and Buckmaster (1976) document higher mean reversion for loss firms. Dichev and Tang (2009) find that higher volatility firms mean-revert more. Thus, under the hypothesis that market fixates on the SRW model, firms with losses and more volatile earnings should demonstrate lower future abnormal returns from the earnings acceleration strategy. In Table 11, Panel A, we compare returns from the acceleration-based strategy for loss versus profit firms. Firms with EPS in quarter t smaller than zero are classified as loss firms and the rest are classified as profit firms. The top quintile of earnings acceleration for loss firms produces an abnormal return of 0.9% while the same for profit firms produces a return of 1.7%. The top minus bottom quintile abnormal return is 0.8% for loss firms while it is 1.8% for profit firms. We test for the significance of difference in hedge returns using an approach similar to Paternoster et al. (1998).[24] The difference in hedge returns between loss firms and profit firms is 1% and statistically significant.

In Panel B, we stratify companies according to past earnings volatility. Firms with above median earnings volatility in each quarter are classified as high volatility firms and the rest are classified as low volatility firms. The top minus the bottom

Table 11
Losses and Earnings Volatility on the Effect of Earnings Acceleration.
This table reports the portfolio results testing the relation between earnings acceleration and stock returns, conditional on losses and earnings volatility. See Table 2 for variable definitions. t-statistics are calculated based on the time-series of the portfolio market-adjusted stock returns.

Panel A: Loss and the effect of earnings acceleration

Test for significance of difference in hedge returns between low earnings volatility and high earning volatility firms:				
Difference in hedge returns	0.006			
z-statistics	2.044			

[24] Specifically, we evaluate the significance of the difference in returns between two groups (G1 and G2) using z-statistic, computed as: $z = \frac{meanG1 - meanG2}{\sqrt{SEG1^2 + SEG2^2}}$, where meanG1 and meanG2 refer to mean returns in hedge return groups G1 and G2; SEG1 and SEG2 refer to the standard errors of returns in hedge return groups G1 and G2.

Please cite this article as: He, S., Narayanamoorthy, G., Earnings acceleration and stock returns, Journal of Accounting and Economics, https://doi.org/10.1016/j.jacceco.2019.101238

quintile abnormal return is 2% for low volatility firms and 1.4% for high volatility firms. The earnings acceleration effect being stronger for profit firms and for low volatility firms (which are firms with lower mean reversion in earnings) is consistent with our prediction, and it provides added corroboration for the hypothesis that the market misses the correlations between earnings acceleration and future earnings growth due to a fixation on the SRW model for earnings.

5. Additional tests

In this section, we address three additional topics: (1) additional ways to enhance returns from the acceleration-based strategy, (2) robustness of the results to the adoption of alternative definitions/deflators, and (3) preliminary tests regarding the implementability of the strategy.

5.1. Enhancing the earnings acceleration strategy returns by considering alternative earnings acceleration patterns

In Section 4 above, we show that the basic earnings acceleration strategy can be enhanced by focusing on profit firms or low earnings volatility firms. Here, we explore additional ways to enhance the strategy. Specifically, following Cao et al. (2011), we partition EAP into six patterns as follows:

Pattern 1: Both current and previous quarter's earnings growth are positive, and current quarter's earnings growth is higher than previous quarter's.

Pattern 2: Current quarter's earnings growth is positive, while previous quarter's earnings growth is negative.

Pattern 3: Both current and previous quarter's earnings growth are negative, and current quarter's earnings growth is higher than previous quarter's.

Pattern 4: Both current and previous quarter's earnings growth are positive, and current quarter's earnings growth is smaller than previous quarter's.

Pattern 5: Current quarter's earnings growth is negative, while previous quarter's earnings growth is positive.

Pattern 6: Both current and previous quarter's earnings growth are negative, and current quarter's earnings growth is smaller than previous quarter's.

We examine the relation between earnings acceleration and stock returns conditional on each of the earnings acceleration patterns. As discussed in Section 4, our theory suggests that the earnings acceleration effect is stronger when mean reversion is lower. Basu (1997) documents that earnings decreases mean revert more than earnings increases. Thus, among the six earnings acceleration patterns, the one pattern which should have the lowest mean reversion, and consequently, the highest future returns, is Pattern 1 (since it is an increase-in-increase pattern). Every other pattern has at least one kind of decrease, and hence will have some degree of mean reversion.[25] Consistent with this prediction, we find that pattern 1 has the largest EAP coefficient among all the patterns (untabulated). In Table 12, Panel A, we show that employing only pattern 1 observations has EAP coefficient of 5.6% (in column three) relative to 1.6% when using the full sample (column one).

While pattern 1 has the strongest earnings acceleration effect due to low mean reversion in earnings, it is not possible to build a hedge portfolio strategy using pattern 1 alone. By construction, pattern 1 observations have positive earnings accelerations and hence negative earnings acceleration deciles will not be represented in a hedge portfolio. As such, we need to combine pattern 1 with patterns 4, 5 or 6 (which, by construction, populate the majority of the negative earnings acceleration deciles) to form a hedge portfolio. Patterns 4, 5 and 6 all have higher mean reversion than pattern 1. However, there is no theoretical guide for which of patterns − 4, 5 or 6 − have relatively lower mean reversion. We find that pattern 5, when combined with pattern 1, produces the largest hedge portfolio returns (Table 12, Panel A, columns five and six). This combination, despite producing higher hedge portfolio returns than the full sample, still yields lower returns in regression tests relative to using pattern 1 alone (3.3% in column five versus 5.6% in column three), which is consistent with our theory. In Table 12, Panel B, we report the hedge portfolio returns for portfolios double sorted (independently) based on EAP deciles and whether the stock belongs to either pattern 1 or pattern 5. A trading strategy that focuses only on pattern 1 or pattern 5 generates one-month hedge return of 2.6%. In contrast, our base strategy only yielded a hedge return of 1.8% (Table 4). Thus, focusing on specific patterns of earnings acceleration can enhance the excess returns by nearly 45%.

5.2. Alternative acceleration definitions/deflators

While we show that the relation between earnings acceleration and stock returns is present under each of the five definitions of acceleration (i.e., EAA, EAP, EAV, SA and PA) in section 2, we only present results for EAP when investigating the relation between earnings acceleration and future earnings growth in section 3. Un-tabulated results show that the relation between earnings acceleration and future earnings growth is present and remarkably robust across each of the other four acceleration measures.[26]

[25] Patterns 2, 3, 5, 6 all have at least one period of negative earnings growth. For pattern 4, although earnings growth in both periods is positive, the change in earnings growth rate is negative (or in other words, there is a decrease in earnings growth rate).

[26] We find that EAV consistently produces even stronger results than EAP.

We also examine how different deflators for EGP and EAP affect our results. Specifically, we examine a total of 16 scenarios, as a combination of using each of the following four variables as deflators for EGP and for EAP: last quarter's stock price, four-quarters-prior stock price, last quarter's total asset, and four-quarters-prior total assets. The returns results remain qualitatively unchanged under these different EGP and EAP deflators.

Lastly, we estimate a Taylor-series expansion of the earnings process using the past 8 quarters' earnings, and define earnings acceleration as the coefficient on the square of the time variable. This definition is analogous to acceleration in physics, and it frees us from the need to use a deflator in defining earnings acceleration. The acceleration variable defined in this manner also positively predicts future abnormal returns (untabulated).

5.3. Implementability of the earnings acceleration strategy

We have already discussed in section 2 the robustness of the strategy to the use of value-weighted portfolios instead of equal-weighted portfolios. We further examine here the implementability of the earnings acceleration strategy along three dimensions — stability of the excess returns over time, the exclusion of low price/low market capitalization stocks and the use of calendar month rebalancing. In Fig. 2, we depict the one-month hedge returns to the earnings acceleration strategy for each of the 176 quarters in our sample. The hedge return is positive in 140 out of the 176 fiscal quarters (80%), which suggests that the relation between earnings acceleration and subsequent stock returns is quite stable over time. This also alleviates concerns that the excess returns are a result of unidentified risk factors. More importantly, Fig. 2 shows that the trading strategy is equally successful in recent years compared to earlier periods. From 2004 to 2015, the strategy yields positive excess returns in 41 out of 48 fiscal quarters (85%). This finding is relevant in view of the recent finding by Green et al. (2017) that a majority of the previously well documented anomalies do not generate returns significant from zero in the post-2003 period.

Notwithstanding that a detailed cost-benefit analysis of the trading strategy is beyond the scope of this study, our second set of results indicate significant positive excess returns of between 0.9% and 1.5% per month even when low priced stocks (less than $5) and/or various partitions of small capitalization stocks (up to $0.5 billion) are excluded from the trading strategy.

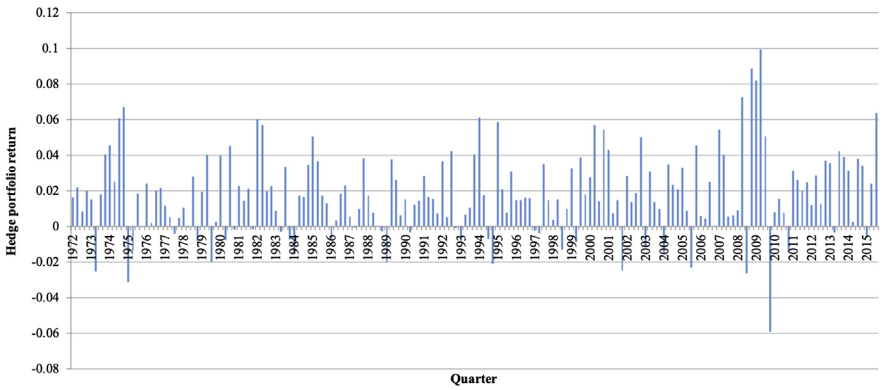

Fig. 2. Stability of Earnings Acceleration Strategy over Time.
This figure depicts the one-month return by fiscal quarter to a hedge portfolio taking a long position in the stock of firms in the highest decile of EAP and an equal sized short position in the stock of firms in the lowest decile of EAP. The x-axis represents fiscal quarters. The y-axis represents the one-month hedge portfolio returns.

Table 13
Alphas and Factor Loadings on Portfolios Sorted on Earnings Acceleration.
This table reports calendar-month average returns to portfolios sorted on earnings acceleration, and results of time series regressions of these portfolios' returns on the Fama and French five factors [the market factor (MKT), the size factor small-minus-large (SMB), the value factor high-minus-low (HML), the profitability factor robust-minus-weak (RMW), and the investment factor conservative-minus-aggressive (CMA)]. t-statistics are reported in parentheses. ***, **, * indicate significantly different from zero at the 1%, 5%, 10% level, respectively.

The trading strategy outlined earlier involved buying and selling stocks two days after an earnings announcement. Such a strategy can potentially lead to significant portfolio rebalancing costs. In our third set of tests, we adopt a conservative calendar month-based rebalancing strategy. At the beginning of each calendar month, we sort stocks of companies that announced earnings in the previous three months into earnings acceleration deciles. Table 13 presents the results of the calendar month rebalancing strategy using equal-weighted portfolio returns.[27] A hedge portfolio going long in the top earnings acceleration decile and short in the bottom decile still yields about 0.9% excess returns over the month-long window. The table also presents factor loadings on the five Fama-French factors.

6. Conclusion

We document that earnings acceleration is an important variable that active investors can focus on in their stock picking efforts to earn significant excess returns. We find economically significant excess returns to an earnings acceleration-based strategy over a quarter following an earnings announcement (with a significant portion accruing over the first month). The returns are robust to a battery of controls for risk and are distinct from previously documented anomalies. In portfolio tests, the incremental excess returns at 1.8% over a month translate to an annualized returns of over 23%. The returns are also remarkably stable over a long period of time (we report results for 176 past quarters).

Our results indicate that the abnormal returns are consistent with investors not incorporating fully the implications of current earnings acceleration for future earnings growth, especially two and three quarters in the future. Notably, current earnings acceleration appears to be associated with significant positive returns in these quarters' earnings announcement windows. Our direct tests of market efficiency also confirm that the positive returns from the earnings acceleration strategy and the positive implications of earnings acceleration for future earnings growth are strongly associated. Last but not least, we show that the results are consistent with investors employing a SRW model for quarterly earnings when the true underlying process is not SRW. The test for whether investors do adopt such a model is only possible, however, in an experimental setting.

Appendix

Correlations between Earnings Acceleration and Future Earnings Growth: Sensitivity to Mean Reversion

Recall that expressions for δ_j, the correlations between earnings acceleration and future earnings growths, were derived under an IMA (1,1) model assumption in Section 4. Sensitivities of the correlations, δ_j, to the IMA (1,1) parameter θ, the extent of mean reversion, are computed analytically below.

$$\frac{d\delta_{t+1}}{d\theta} = \frac{5\theta^4 - 6\theta^3 + 6\theta - 5}{4(\theta^2+1)^{\frac{3}{2}}(2\theta^2 - 3\theta + 2)^{\frac{3}{2}}}$$

$$\frac{d\delta_{t+2}}{d\theta} = \frac{5\theta^4 - 6\theta^3 + 6\theta - 5}{4(\theta^2+1)^{\frac{3}{2}}(2\theta^2 - 3\theta + 2)^{\frac{3}{2}}}$$

$$\frac{d\delta_{t+3}}{d\theta} = \frac{\theta^4 - 3\theta^3 + 3\theta - 1}{4(\theta^2+1)^{\frac{3}{2}}(2\theta^2 - 3\theta + 2)^{\frac{3}{2}}}$$

$$\frac{d\delta_{t+4}}{d\theta} = \frac{4\theta^4 - 3\theta^3 + 3\theta - 4}{4(\theta^2+1)^{\frac{3}{2}}(2\theta^2 - 3\theta + 2)^{\frac{3}{2}}}$$

In the range of $0 < \theta < 1$, the derivatives of δ_{t+1}, δ_{t+2} and δ_{t+4} are always negative. While the derivative of δ_{t+3} is not always negative, it is very small, which makes the correlation between earnings acceleration and future earnings growth nearly flat lying within a narrow range of 0.33–0.35.

Capital markets research in accounting: Lessons learnt and future implications

Christo Karuna

Monash University, Australia

A B S T R A C T

I review the capital markets literature in accounting by describing the journey taken by researchers since the inception of this stream of research in the late 1960s. Based on a discussion of topics related to the relation between earnings and stock returns, I show how thinking has evolved depending on changing paradigms, methodologies, and data availability. What is clear from a review of the literature is that the usefulness of earnings in determining firm value is both contextual and broadening over time with changes in the global environment. Thus, more research needs to be conducted on a broader notion of earnings that appeals to not just the shareholder but a wide range of firm stakeholders.

1. Introduction

This paper provides an overview of the empirical capital markets literature in accounting based on a keynote speech I gave at the 2018 Financial Markets and Corporate Governance Conference on lessons learnt in capital markets research in accounting and future implications.[1] There is a vast array of topics that fall under the umbrella of capital markets research in accounting; however, my discussion focuses narrowly on the relation between accounting earnings and stock returns. Specifically, I discuss in this paper what, in my opinion, are lessons learnt from important research topics on the stock return-earnings relation in this literature that would be of interest to a finance audience. Thus, the purpose of this paper is to provide an overview of the journey taken by capital markets researchers in accounting since inception that would be informative (in terms of breadth and depth) to a finance audience.

I begin this overview with a summary of the historical development of the capital markets literature in accounting in section two. In section three, I discuss two main areas of capital markets research in accounting that would be of interest to finance researchers, namely, tests of capital market efficiency and fundamental analysis and accounting-based valuation. Development of these two topics mirror that in the finance literature, with the latter topic closely related to the behavioural finance literature. In section four, I discuss current research that evolved from changes in paradigm, methodology, and data availability. I conclude this overview in section five, where I also discuss future implications and provide suggestions for future research.

2. Historical development of capital markets research in accounting

Capital markets research in accounting blossomed in the late 1960s after the development of the Efficient Markets Hypothesis (EMH) and event study methodology at the University of Chicago by Eugene Fama and his colleagues (Fama et al., 1969). Seminal studies in accounting by Ball and Brown, (1968) and Beaver, (1968) on the stock return-earnings relation, combining insights from Positive Economics Theory, EMH, and the Capital Asset Pricing Model (CAPM), paved the way for researchers examining accounting

E-mail address: christo.karuna@monash.edu.

[1] This paper is not exhaustive in its discussion of topics. For detailed insights from this literature the reader is referred to several reviews, namely, Bradshaw, (2011), Dechow et al., (2014), Kothari, (2001), Barth et al., (2001), Healy and Palepu, (2001), Holthausen and Watts, (2001), Lee, (2001), Landsman, (2007), Richardson et al., (2010), Leuz and Wysocki, (2016)), Ryan, (2016).

Available online 06 March 2019

earnings within the capital markets context. What followed was a plethora of studies in the accounting literature in the 1970s and 1980s that examined the stock price reaction to an earnings announcement over a short window ranging from a few minutes to a few days (short-window tests), and long-window tests that examined the same relation over a period of one to five years in studies conducted in the late 1980s and 1990s, a period that witnessed research in fundamental analysis, valuation and tests of market efficiency based on challenges to EMH.

The 1970s, 1980s, and 1990s were also periods when methodological research dominated capital markets research in accounting. Topics examined in this area are earnings response coefficients, properties of time series of earnings, management and analyst earnings forecasts, earnings growth rates, statistical inferences, and discretionary/non-discretionary accruals models, drawing inferences from event studies, post-earnings-announcement drift (PEAD), long horizon returns to accruals management and analyst forecast optimism, and cross-sectional tests of return predictability.

The 1990s and 2000s witnessed research conducted on the following topics: motivation for fundamental analysis, value-relevance, valuation models, Regulation Fair Disclosure (Reg. FD), Sarbanes-Oxley Act (SOX), Fair Value accounting, implied cost of capital, recognition versus disclosure, impact of governance, large shareholder ownership, stewardship and valuation roles of earnings, and debt contracting.

In the next section I discuss two main areas of capital markets research in accounting that dominated the capital markets research in accounting literature, namely, tests of capital market efficiency and fundamental analysis and accounting-based valuation.

3. Two main areas of capital markets research in accounting

3.1. Tests of capital market efficiency

Tests of capital market efficiency in accounting parallel those in economics and finance. An efficient market is one in which security prices reflect all available information (Fama, 1970). In accounting, researchers have largely focused on examining how well security prices reflect information contained in earnings, specifically, via the earnings announcement. This is important because security prices are associated with wealth allocation in society, and therefore, knowledge of how accounting is impounded in the security price will enable researchers to gauge its usefulness in wealth creation.

A large body of research in capital markets research in accounting is dominated by tests of EMH in the form of both event studies, as well as cross-sectional tests of the predictability of returns or the anomalies literature; thus, they examine the information content of earnings. Event studies examine the impact of an earnings announcement on the level or variability of security prices or trading volume and are “joint tests of market efficiency and the model of expected rates of return used in estimating abnormal returns” (Kothari, 2001). Studies that provide evidence on the informativeness of earnings announcements are Ball and Brown, (1968), Beaver, (1968) and Amir and Lev, (1996), to name a few. Specifically, these studies document a significant positive relation between the sign of an earnings change, at an earnings announcement, and abnormal stock return. The stronger the relation, the more informative are earnings as well as the better the quality of the earnings expectation model employed in the test.

In contrast to event studies, association studies in accounting examine the relation between earnings and stock returns over a longer period, for example, a year. Such studies allow for the possibility for other information to confound the stock returns-earnings relation. Thus, rather than measure the informativeness of earnings with respect to stock prices, association studies examine whether and how quickly earnings capture changes in the information captured in stock returns over the period. Studies in this stream of research include Ball and Brown, (1968), Collins and Kothari, (1989) and Easton and Harris, (1991), to name a few. These studies provide evidence that annual earnings are not sufficiently timely as information (e.g., quarterly earnings) is leaked to the market before annual earnings announcements. Thus, the evidence in these studies suggests that stock prices lead earnings in reflecting new information. Several studies also document a post-earnings announcement drift (PEAD) (e.g., Ball and Brown, 1968; Bernard and Thomas, 1989; 1990), which shows a lag with which earnings are impounded in stock prices. For example, in the first study to document PEAD, Ball and Brown, (1968) document an asymmetric adjustment to the nature of the news contained in earnings announcements – bad news are reflected in stock prices after several months, indicating an underreaction and slow adjustment of the market to earnings. Among other studies, Bernard and Thomas, (1989); (1990) attribute PEAD to delayed response to new information.

Several studies compare the informativeness of earnings and cash flows and provide evidence that earnings are more informative than cash flows (e.g., Dechow, 1994). These studies conclude that the accrual component of earnings contributes to the greater informativeness of earnings relative to cash flows.

The stock return-earnings relation, labelled the earnings response coefficient (ERC), has been documented to be weak in the literature, ranging from 1 to 3 (e.g., Easton and Zmijewski, 1989; Kormendi and Lipe, 1987). Several studies provide cross-sectional and time-series evidence on the determinants of ERCs (e.g., Collins and Kothari, 1989; Easton and Zmijewski, 1989; Kormendi and Lipe, 1987). The evidence in these studies show that researchers need to control for the effects of earnings persistence, risk, and growth to examine the impact of a variable on ERC. Other studies document that factors related to a firm's strategy like its life cycle and business strategy (Anthony and Ramesh, 1992) and industry product market competition (Baginski et al., 1999; Biddle and Seow, 1991).

Several explanations have been forwarded for the low magnitude of the stock return-earnings relation, namely, that prices lead earnings in terms of reflecting all relevant information, and thus reducing earnings informativeness, inefficient capital markets that fail to accurately capture an earnings surprise, accounting distortions that generate noise in earnings and deficient Generally Accepted Accounting Principles (GAAP) in capturing relevant factors that influence firm market value like intangibles, and transitory components in earnings like one-off gains and losses and asset sales.

3.2. Fundamental analysis and accounting-based valuation

Following developments in behavioural economics and finance, accounting scholars embarked on another stream of research that examined whether information contained in earnings could be used to create/enhance wealth incrementally to the stock price. For example, behavioural finance models of inefficient markets (Barberis et al., 1998; Daniel et al., 1998; Hong and Stein, 1999) question the veracity of EMH - according to Fama, (1965), new information will be instantaneously and fully reflected in stock prices based on competitive behaviour among rival rational, profit-maximising actors operating in a competitive context.

Similarly, accounting researchers have also produced evidence that is inconsistent with EMH. Ample evidence challenging the legitimacy of EMH was provided to stimulate research into the lag with which accounting information is impounded into stock prices. These researchers claim that stock returns are predictable using the time-series properties of earnings and/or properties of earnings forecasts, and that trading strategies could be formed using accounting information to maximise wealth. This stimulated fundamental analysis research, which was focused on identifying mispriced securities for investment purposes. The mispricing of these securities is dependent on the difference between a firm's current security price and the intrinsic value of the firm, which in turn is determined by the information contained in the firm's current and past financial statements as well as industry and macroeconomic data.

Different valuation models surfaced to compute a firm's value. The residual income model by Ohlson, (1995) and Feltham and Ohlson, (1995), is derived from the dividend discounting model, and expresses value as the sum of the current book value and the discounted present value of expected abnormal earnings, defined as forecasted earnings minus a capital charge equal to the forecasted book value times the discount rate.

The usefulness of earnings in determining a firm's value has also been extensively examined in the literature. I next discuss two popular topics in this literature that are concerned with how the accounting system influences the usefulness of earnings in determining firm value: accrual accounting and accounting conservatism.

3.2.1. Accrual accounting

The stock price is generally computed as the present value of future cash flows, discounted at the cost of equity capital. Finance researchers typically regard cash flows as superior to earnings in valuing securities, either because they feel that earnings can be manipulated and is subject to accounting distortions like the immediate expensing of research and development expenditure as required by GAAP. However, as discussed above, the market reacts to earnings news (announcements). Thus, it is evident that information contained in earnings is useful to value stock prices beyond cash flows.

A vital component of earnings which enhances its timeliness, and thus its usefulness to signal future cash flows more than past cash flows is accruals. Dechow, (1994) provides evidence that accruals dominates cash flows in predicting future cash flows. Under the assumption of efficient markets, Dechow estimates the R squares from annual regressions of returns on earnings or cash flows and finds that the explanatory power of earnings dominates that of cash flows. According to the Statement of Financial Accounting Concepts No. 8 of the Financial Accounting Standards Board (FASB 2010, page 4), "Accrual accounting depicts the effects of transactions, and other events and circumstances on a reporting entity's economic resources and claims in the periods in which those effects occur, even if the resulting cash receipts and payments occur in a different period." This description illustrates the completeness with which accruals captures past and future cash flows compared to current cash flows. Dechow et al., (2014) attribute the timeliness of accruals to their ability to anticipate future cash inflows based on the Revenue Recognition Principle, which allows firms to recognise revenue and record an asset before it is received, as long as it is realisable and earned. Dechow et al. also list other features of accruals that reduce earnings volatility and increase earnings persistence relative to cash flows. First, accruals are able to anticipate future cash outflows as firms are required to anticipate certain costs that have not yet been incurred (labelled a liability). Second, the recognition of expense can be delayed even though cash has been paid. For example, inventory can be capitalised when paid for with cash, and labelled an asset, and becomes an expense only when it is sold (or impaired). Finally, the recognition of revenue can be delayed even though cash has been received. For example, when a firm has not yet provided the good or service, but has received cash for it from the customer, the firm has to defer recognising the revenue (and hence, labelled a liability).

Accounting researchers also examined components of earnings to gauge whether they are more or less useful in explaining stock returns. For example, Bradshaw and Sloan, (2002) show that by removing transitory components of earnings (resulting in "proforma or street earnings"), earnings' ability to reflect underlying firm value is significantly enhanced as they are more closely related to stock prices when they are more persistent in nature. In an earlier study, Fairfield et al., (1996) find evidence that financial statement items relating to extraordinary items, special items, and discontinued operations are less persistent than income items that are more persistent.

Sloan, (1996) finds evidence that 84% of current earnings persist into the following year's earnings. However, he shows that the cash component of earnings is more persistent (and thus of higher quality) than the accruals component of earnings. Due to the reversal of accruals, possible managerial manipulation, and accounting rules, accruals contain measurement error, which contributes to its lower persistence compared to the cash component of earnings. Thus, investors should consider these issues when making their decisions. Sloan find that stock prices act as if investors are fixated on earnings while failing to consider fully information in the accrual and cash flow components of current earnings until the information influences future earnings. Therefore, if the accrual component is unusually high (low), investors tend to experience negative (positive) abnormal stock returns around earnings announcements when the mispricing is corrected in the future, as the investors would have overpriced (underpriced) stocks in which the accrual component is relatively high (low) due to not anticipating the lower persistence of earnings performance attributable to the accrual component of earnings. Sloan advocates that a trading strategy of going long in stock of firms with relatively low levels of accruals and short in the stock of firms with relatively high levels of accruals will yield positive abnormal stock returns.

3.2.2. Accounting conservatism

Statement of Financial Accounting Concepts No. 2 of the Financial Accounting Standards Board defines conservatism as “a prudent reaction to uncertainty to try to ensure that uncertainties and risks inherent in business situations are adequately considered. Thus, if two estimates of amounts to be received or paid in the future are about equally likely, conservatism dictates using the less optimistic estimate…” (FASB, 1980), Accounting conservatism reflects the prudency with which the accounting system recognises transactions that affect earnings in that it requires a high degree of verification before making an irrefutable claim to earnings. Thus, accounting conservatism provides guidance in the event of uncertainty or when the need for estimation arises. Likely losses and expenditures should be recognised as soon as they are identified and incurred, respectively. Similarly, under the revenue recognition principle, revenue can only be recognised when it is verified. Thus, due to the uncertainty pertaining to accrual accounting, future revenue or costs are recognised only when there is certainty regarding the associated transaction. For example, under a credit sale transaction, overestimating an allowance for doubtful collection of payment is encouraged, and the sale is only allowed to be recognised when the transaction actually takes place, thus providing a more accurate picture of the accounts receivable account. In addition to its effect on earnings, accounting conservatism affects how assets are reported. For example, in valuing inventory, firms are required to report inventory at the lower of its historical cost or its current market value.

Two types of conservatism have been identified in the accounting literature, namely, unconditional conservatism and conditional conservatism. Unconditional conservatism does not depend on news. For example, unconditional conservatism is illustrated via the immediate expensing of research and development expenditure. Conditional conservatism refers to a property of earnings that is dependent on news. An example of unconditional conservatism is the asymmetric recognition of gain and loss contingencies. Basu, (1997) is the first study to document the asymmetric timeliness property of earnings in that earnings reflects the “bad news” reflected in negative stock returns more quickly than the “good news” reflected in positive returns. Basu also finds that negative earnings changes are less persistent than positive earnings changes. Studies show that accounting conservatism reduces the persistence and predictability of earnings, encourages earnings management, reduces the forecast accuracy of analysts, and may reduce the value relevance of earnings (Ruch and Taylor, 2015). Therefore, accounting conservatism has the tendency to reduce the usefulness of earnings from a valuation perspective.

Overall, accounting conservatism results in potentially understated assets and revenue, and overstated liabilities and expenses, which results an understatement of the book value relative to market value of equity as well as lower reported net income and future financial benefits.

4. Current capital markets research in accounting

Prior capital markets research in accounting has generally focused on whether and how earnings mapped into stock returns as well as how earnings is useful to investors. The evidence shows that trading volume and abnormal stock returns are approximately double around earnings announcements, thus showing that earnings announcements contain information that is used by investors to make their trading decisions. However, earnings announcements could lack information value if earnings are computed with measurement error or if the information in earnings announcements could be conveyed through more timely sources (e.g., dividend announcements, management forecasts). Dechow et al., (2014) provide evidence that the information content of earnings announcements was the highest during the 2001–2012 period.

Notwithstanding the documented usefulness of earnings in determining firm value, several studies have challenged earnings' usefulness in capturing a broader notion of firm value, specifically, the non-financial component of firm value. For example, Lev and Zarowin, (1999) show that the usefulness of accounting numbers declined over the 20 years prior to their study. They attribute this to the failure of the accounting system to adequately reflect innovative activities. The internet bubble in the late 1990s witnessed a lack of timeliness of earnings in explaining stock prices. This has prompted a new stream of research scrutinising financial statements to generate new insights using advanced methodological developments. I discuss next two research topics of current interest in the literature to both finance and accounting academics.

4.1. Textual analysis of disclosures

First, in order to examine more closely qualitative and text-based narrative information (which were previously difficult to use) contained in important disclosure, management, discussion, and analysis (MD&A), 10-K footnote disclosures, and conference call transcripts, finance and accounting researchers have started using recent advances in textual analysis, computational linguistics, and natural language processing to construct new measures for narrative disclosures. The availability of rich textual datasets via the Edgar filing system, SEC comment letters, financial analyst reports, and conference call transcripts provide researchers with additional sources of information beyond financial statements to determine firm value.

The studies in finance and accounting that helped researchers advance their knowledge of textual analysis are Frazier et al., (1984), Antweiler and Frank, (2004), Das and Chen, (2007), Tetlock, (2007), Li, (2008); (2010), and (Loughran and McDonald, (2011); (2013); (2014); (2015). Other studies have provided evidence on the information content of textual disclosures and have generally found that they are informative in terms of both fundamentals and market reactions. For example, some studies show that optimistic information contained in earnings releases (e.g., Davis et al., 2012; Henry, 2008) and 10-K SEC filings (e.g., Loughran and

McDonald, 2011) is associated with a positive reaction by the market. Davis et al., (2012) find evidence that optimistic language in earnings press releases is positively related with future earnings (specifically, return on assets) and stock return. They also find that median earnings press length increased by 90% from 1998 to 2003. This finding is consistent with that of Francis et al., (2002), who document a significant increase in the number of words in earnings press releases from 1980 to 1999.

In contrast, Li and Ramesh, (2009) find a significant market reaction surrounding 10-Q filings that is limited to filings that release earnings information for the first time. They also find a market reaction to information contained in 10-K reports only when they are filed around calendar quarter-ends. Thus, the evidence provided by Li and Ramesh, (2009) shows little market reaction and, therefore, limited information content in the filings beyond what the market already knows. Li, (2010) attributes this difference between the findings in Li and Ramesh, (2009)) and both Loughran and McDonald, (2011) and Davis et al., (2012) to the consideration of the tone of disclosures in the Loughran and McDonald, (2011) and (Davis et al., (2012) studies. Also focusing on the tone of disclosure, Kothari et al., (2009) find that a favourable textual disclosure tone is associated with lower firm risk (proxied for by the cost of capital, stock return volatility, and analyst forecast dispersion).

Textual analysis of qualitative information enables researchers to gauge useful information associated with firm value beyond the aggregated nature of the earnings announcement. Developments in behavioural economics have identified cognitive biases of individuals and how these influence decision-making (e.g., Kahneman, 2003). Textual analysis enables researchers to gauge managerial biases, which could be useful to investors in assessing firm operating, investing, and financing decisions.

Textual analysis enabled researchers to examine three disclosure characteristics of interest, namely, the amount, tone, and transparency (readability) of the disclosed information. For example, studies that examine the impact of transparency/readability and tone of disclosure on future earnings are Li, (2008) and (2010), respectively. Lee, (2012) and Lawrence, (2013) examine the relation between transparency/readability on market pricing and Davis et al., (2012), Henry, (2008), and Li, (2010) are some papers that examine the relation between the tone of disclosure and market pricing.

4.2. Implied cost of equity capital

The second research topic of current interest among both finance and accounting researchers is the implied cost of capital. The cost of equity capital has historically been computed using the firm's ex ante expected stock return, based on tests of asset pricing theory, and proxied for using ex post realised return due to the unobservability of expected returns; in an efficient market where risk is suitably priced, the average ex post realised returns are arguably an unbiased estimator of ex ante expected returns. However, several researchers have emphasised that realised returns are a noisy proxy for expected returns (e.g., Elton, 1999; Froot and Frankel, 1989; Sharpe, 1978). To address this deficiency, more recent studies (e.g., Claus and Thomas, 2001; Easton, 2004; Ohlson and Juettner-Nauroth, 2005) advocate the use of the implied cost of capital to estimate expected returns – these studies define the implied cost of capital as the discount rate that the market uses to discount the expected cash flows of the firm. This measure estimates expected return directly from stock prices and cash flow forecasts. To proxy for cash flow forecasts, the literature uses analysts' earnings forecasts. However, other studies (e.g., Easton and Monahan, 2005) show that the implied cost of capital computed using analysts' earnings forecasts has little predictive power for future realised returns after controlling for cash flow news and discount rate news. Hou et al., (2012) use earnings forecasts generated by a cross-sectional model to proxy for cash flow expectations and find that their model captures significant variation in earnings performance across firms. They also find higher earnings response coefficients using their approach than analysts' forecasts, suggesting that the earnings forecasts from their cross-sectional model represent a better proxy for market expectations of future earnings.

Gebhardt et al., (2001) is one of the first few studies to compute a market implied cost of capital using a discounted residual income model and market prices.[2] Consistent with Claus and Thomas, (2001), they find that the average implied risk premium for stocks in the U.S. equity market during the 1979–1995 period was much lower than the ex post risk premium. Gebhardt et al., (2001) also document that certain industries have a higher discount rate, but that this effect disappears when realised returns are used to proxy for expected returns. Finally, they find that, after controlling for industry effects, firms with lower market-to-book ratios, higher forecasted growth rates, and lower dispersion in analyst forecasts are assigned a higher risk premium by the market.

5. Conclusions and future implications

Capital markets research in accounting has come a long way. From its roots in examining the relation between earnings and stock prices based on market efficiency to newer ways of thinking and testing based on challenges to market efficiency and more advanced tools and datasets, this stream of research covers a vast literature spanning many topics. Researchers on this topic have generated insights based on their respective beliefs pertaining to whether the capital market is efficient or not. Thus, there is no "correct" choice between conflicting insights; instead the insights depend on the assumptions pertaining to how the capital market behaves. In this review, I have discussed what I believe to be topics on the relation between earnings and firm value of interest to a finance audience. The review is structured in such a manner so as to give the reader a high-level picture of the journey taken by capital markets researchers in accounting from its inception in the late 1960s.

What is evident from the advances in the literature on capital markets research in accounting is a widening of the definition of the

[2] The residual income model is equivalent to the dividend discount model with an indefinite horizon. The reader is referred to Ohlson, (1995) and Feltham and Ohlson, (1995) for a more detailed discussion of the residual income valuation model.

usefulness of earnings over time. With an ever changing world, especially one where firm assets are mainly of an intangible nature, and where firms operate in a volatile, uncertain, complex, and ambiguous (V.U.C.A.) environment, the hurdle is becoming higher for earnings to display its usefulness in influencing firm value. Although much research has focused on the usefulness of earnings in determining firm value via stock prices, a broader notion of firm value is gaining traction in the literature. Recent assertions by Baruch Lev and his co-author, Feng Gu, that traditional financial reporting has lost its relevance is a wake up call to researchers who previously took for granted earnings usefulness in influencing firm value. Lev and Gu show and argue in their book titled “The End of Accounting and the Path Forward for Investors and Managers” (Lev and Gu, 2016) that financial statements have lost their usefulness in providing necessary information to investors to make necessary investment decisions. According to these authors, the financial report only provides 5% of the information that investors base their decisions on. They propose a “Value Creation Report” that provides information on the strategic, value-enhancing resources (assets) like patents, brands, technology, natural resources, operating licences, customers, business platforms available for add-ons, and unique enterprise relationships, rather than on the commoditised plant, machines, or inventory that are reported on corporate balance sheets but are based on a traditional view of the corporation based on the industrial age that does not accurately consider intangible and intellectual assets. While Lev and Gu's assertions are bold and paints a bleak picture of current capital markets research in accounting, and more research needs to be conducted to verify their claims, it is clear that more research needs to be conducted on enhancing the usefulness of accounting information reported in financial statements for investment decisions. For example, it is conceivable that a “one-size-fits-all” approach to the valuation role of earnings is misguided and that there is a contextual aspect to earnings usefulness for valuation purposes. It is likely that earnings may not be as useful for valuation purposes in certain firms or industries (e.g., growth firms or industries where intangible and intellectual assets, or innovation, matter). More research is needed on a broader notion of earnings usefulness to capture a firm's intangibles, and even competitiveness in the industry, to more comprehensively and accurately reflect market value.

Related to the above declining usefulness of earnings under the traditional financial reporting framework, an important development in the post-global financial crisis (GFC) world is the gaining importance of a multistakeholder perspective. Prior to the GFC, firms have largely catered more to, and at times fixated on, the shareholder relative to other stakeholders. With an ever empowered community, employee, supplier, and customer, firms are seeing the need to balance different major stakeholder interests. An implication of this is that financial reports should be as complete and comprehensive enough that all these different stakeholders see the value of the reported information related to their interests in the firm and to help their investing decisions. It is a challenge for researchers to adopt this broader notion of earnings usefulness in influencing firm value.

Integrated reporting is another response along this vein that appears to be gaining mileage in the literature. It adds value to a firm by highlighting how non-financial aspects of the firm can drive long-term growth in firm value. Investors are increasingly demanding non-financial data to gauge a firm's valuation prospects as such data provides useful information about the firm's sustainable growth based on its appeal to a broad spectrum of stakeholders. Integrated reporting is principally aimed at the long-term investor and advances the mission of the firm from that of one which is financially driven (e.g., profits) to one that has a higher purpose that benefits the wider community. Such a perspective may entail sacrificing short-term financial capital to increase a firm's profit potential in the long term. It also embraces a wider notion of value, shared value – rather than focus on a firm's value, the firm focuses on shared value between the firm and its key stakeholders whereby every stakeholder's value, including the firm's, is maximised in the long term via sustainable relationships among each other. This would be consistent with initiatives by the United Nations (UN) via its UN 2030 Sustainable Development Goals (SDGs), based on which 193 countries agreed in 2015 to work towards these 17 goals. This increases the likelihood that firms have a responsibility to contribute towards attaining these goals and hence broadening their activities, which in turn increases the relevance of accounting information for a broader notion of firm value. Thus, I encourage researchers to examine these issues which tie earnings usefulness to societal welfare.

Relatedly, further research should be conducted on examining social media to obtain additional useful accounting information in addition to that provided in financial reports. Social media has empowered different stakeholders in that a firm's value could be significantly influenced by the information conveyed through social media by a firm's stakeholders that could influence the market's estimate of how the future cash flows would be influenced by the disclosed information. Similarly, a firm could disclose important information in a timelier manner through social media to its key stakeholders, which could influence the nature of its relationships with the stakeholders, and which in turn could signal to the market future cash flow consequences. Hutton et al., (2015) find that the negative stock price reaction to announcements about product recalls is less pronounced for a firm with interactive social media. They also find that the negative stock price reaction to a recall is attenuated with the number of tweets by the firm but exacerbated with the number of tweets by other users. More research on the relation between social media use as a disclosure channel and firm value could yield useful insights.

Disaggregated line items in financial statements are potentially useful in impacting a broader notion of firm value that also considers multiple stakeholder perspectives. Such line items (e.g., revenue) also related more to processes that precede the reporting of earnings and hence are timelier than bottom-line earnings. Furthermore, focusing on these line items can enable a firm to determine how value can be created or enhanced from the perspectives of its different key firm stakeholders, (e.g., employees, customer, and suppliers). An implication of this assertion is that multiples such as price-per-customer, price-to-sales, and other similar disaggregated measures may be more useful in determining firm value than the much touted price-earnings ratio. Significant progress has made on fundamental analysis research pertaining to how different line items can influence firm value. I encourage researchers to extend this stream of research.

5.1. Capital market implications for the Pacific Basin region

While regulations like the International Financial Reporting Standards (IFRS) seek to maintain uniformity worldwide, this poses a challenge in regions that are clearly different to each other. This calls for a more nuanced and context-specific reporting format in financial reports. The Pacific Basin is one example of a region where there is rich diversity in the environment in which firms operate. For brevity, I will discuss implications for two major economies in this region, China and India. China with its emphasis on manufacturing whereas India with its emphasis on services is one important difference between these two large emerging economies in the Pacific Basin. Another key difference is the higher proportion of foreign institutional ownership in the Indian economy compared to the Chinese economy. The Chinese stock market is relatively young and therefore likely more volatile compared to the mature Indian stock market. Consequently, the Chinese stock market does not play as prominent role in the Chinese economy as the Indian stock market does in the Indian economy. According to the Brookings Institution, only 5% of corporate financing is funded by equity in China, where there is much reliance on bank loans and retained earnings. Given these differences in the investor profile, type of industries, age of the market, and the importance of equity financing between the Chinese and Indian economies, more research needs to be conducted on the usefulness of accounting information, like earnings, for determining firm value in these two markets.

Much of the capital markets research in accounting has been conducted based on the U.S. equity market. It is possible that the Pacific Basin could yield additional insights beyond what have been generated in the current literature. For example, it would be useful to examine the role played by state ownership on earnings usefulness. Additionally, government protection via state ownership could influence accounting conservatism. It is also conceivable that the equity investor may not be as important in China as in the U.S. Consistent with this notion, other firm stakeholders like debtholders or even the government, could be more associated with accounting information like earnings than in the U.S. This could lead to less earnings usefulness for the equity investor in China compared to the U.S., and an appeal to a broader stakeholder base. These issues could be examined by researchers. Finally, the greater proportion, and importance, of family ownership in China, with its longer horizon, could yield different findings to empirical tests of relations conducted based on the U.S. stock market, which is dominated by more institutional investors, who have a shorter horizon. An implication of this difference between the U.S. and China is that earnings could be more related to short- than long-term firm value in the U.S. and vice versa for China. Whether anomalies documented in the literature (e.g., the accruals anomaly and PEAD) based on U.S. data are more pronounced in an emerging economy like China is worthy of empirical investigation. Similarly, possible behavioural biases such as the underreaction or overreaction to accounting information by developing capital markets in the Pacific Basin are also worthy of examination.

In conclusion, capital markets in accounting research has generated valuable knowledge on the concept of firm value. The traditional premise that cash flows are superior to earnings, or other accounting information, in influencing firm value can be dispelled based on important findings in the literature. The role of non-financial information in capital markets should also not be underestimated. Given that the world is changing at a fast pace, and becoming increasingly diverse along many different dimensions, this stream of research promises attractive future opportunities for finance researchers.

Abstract

This paper provides the first *direct* evidence of the impact of enforcing insider regulations on the informativeness of insider trades and stock price efficiency across 44 countries with varying levels of insider trading regulations. Results suggest that insider purchases earn abnormal profits, especially in countries with active enforcement of insider trading regulations. We further show that while insiders trade less before earnings announcements in countries with active enforcement, their stock prices react more to earnings news than those in countries without active enforcement. Overall, our results support the view that effective insider trading regulation promotes price efficiency.

1. Introduction

Whether or not insider trading should be regulated has been the subject of a long-standing debate among researchers and policymakers. Opponents of insider trading regulation contend that allowing insiders to benefit from their information advantage in trading promotes more informationally efficient financial markets (Manne, 1966; Carlton and Fischel, 1983; Leland, 1992; George and Seyhun, 2002). Proponents of insider trading regulation, however, argue that unrestricted insider trading can adversely affect the incentives of outside investors to acquire and produce information, hence making stock prices less informationally efficient (Fishman and Hagerty, 1992; Khanna *et al.*, 1994). Bhattacharya and Daouk (2002) make the first attempt to look at varying enactments and first-time prosecution of insider trading laws across 103 countries. They find that only first-time legal prosecution of insider trading laws can reduce a country's cost of equity, thereby lending support to insider trading regulation.[1] However, their study provides no direct evidence on the informativeness of insider trades across different regulation regimes, the potential tradeoff between the informational benefit of insider trading and the cost of reduced information acquisition, and the overall impact of insider trading regulation on price efficiency. Thus, the purpose of our study is to address all these important issues and provide evidence that helps settle the debate.

Our research represents the first to directly evaluate and compare the information contents of insider trading activities across different regulation and enforcement regimes. We exploit a newly available global dataset that contains information of global insider transactions of senior corporate executives and corporate directors from 44 countries over the period of 2007 to 2013. By examining insider trading activities in this large number of countries with varying levels of insider trading enforcement, we seek to provide the first comprehensive evidence on insider trading activities and their informativeness across different markets, to understand the role of insider trading regulation in determining insider trade informativeness, and to assess the relation between insider trading regulation and stock price efficiency.

We start by examining insider trading activities and their informativeness across different insider trading regulation regimes. All 44 countries in our sample have insider trading laws, but enforcement of insider trading laws varies widely across these countries. To measure the extent to which a country enforces its insider trading regulation consistently and rigorously, we construct an "Active Enforcement" variable that is based on the prosecution of insider trading in a country during the sample period of 2007–2013.[2] Active Enforcement is a binary variable that equals

[1]Our unreported results show that first-time prosecution has no effect on the informativeness of insider trading.

[2]We have also constructed the same variable using information 5 years prior to 2007. Both measures yield qualitatively similar results. Given varying start years of the availability of insider transactions for the sample of countries, we choose to report the results based on the construct for the sample period.

one if the country is actively enforcing its insider trading regulation in that it has at least one insider trading prosecution case during the sample period; otherwise, it is zero. We measure the informativeness of insider trades based on abnormal stock returns subsequent to insider transactions. For each country, we compute the average cumulative returns of stocks traded by insiders for buys and sells, separately, in excess of the country index return for varying periods of 5–120 days following the day of insider trades.

Several results emerge from the comparison of the large number of insider trades across the countries. First, corporate insiders trade actively, and their trades, particularly their buy transactions, are informative, and the effect is more pronounced in countries with active enforcement of insider trading regulations than in countries without.[3] Abnormal returns associated with insider buy transactions over the different periods from 5 to 120 days subsequent to insider transaction dates are positive and highly significant, while those associated with sell transactions show no robust evidence. Furthermore, insider trading informativeness is related to various country-level economic and legal characteristics, but the legal characteristic variables such as the rule of law, the general effectiveness of law enforcement, investor protection, and the quality of government do not substitute for the effects of enforcement of insider trading regulation. Second, insider trading regulations do not seem to affect the level of insider trading activities. The results show no significant difference in overall insider trading activities (scaled by a country's stock market capitalization) between countries with and without active enforcement of insider trading regulations.

Why does active insider trading regulation result in more, not less, informative insider trades? How does insider trading regulation affect stock price efficiency? To answer these questions, we examine insider trading activities around an important corporate event – corporate earnings announcements – and also investigate the relation between insider trading regulation, insider trading activity, and market reaction to earnings news. In countries with active enforcement of insider trading regulations, insiders trade less actively before corporate earnings announcements, but market reactions to earnings news are stronger. These findings suggest that active enforcement of insider trading regulation deters insiders from exploiting non-public and material corporate information in their stock trading, but seems to facilitate market efficiency. Furthermore, insiders trade actively before earnings announcements in countries without active enforcement of insider trading but with lockout period requirements, implying that active enforcement of insider trading regulation, not insider trading regulation itself, determines insider trading activity around earnings announcements. All these results are robust after controlling for various country, market, and institutional characteristics.

[3]U.S. studies such as Ravina and Sapienza (2010) and Cohen *et al.* (2012) also find that insiders still have the ability to trade on private information, in spite of the U.S.'s rigorous enforcement of insider trading regulations.

Finally, to further corroborate the informativeness of insider trades, we examine insider profits around earnings announcement dates. If insiders are able to exploit their information advantage, they should be able to make more profits from trading prior to earnings announcements. We find that insider trading profits are larger before earnings announcements in countries with active enforcement of insider trading regulation, but no difference in insider profits before and after earnings announcements in countries without enforcement. Therefore, these findings indicate that insider trading activities are informative only in countries that enforce their insider trading regulations. In other words, insiders from countries without enforcement could exploit their information advantage, such as corporate earnings news, in their trades, but market reactions to such news are weak, thereby resulting in noisier stock prices, which in turn, reduce the potential information advantage of insiders and subsequently lower the informativeness of their trades.

Our study makes several contributions to the literature. First, the newly available insider trading database from a broad spectrum of countries affords us the opportunity to empirically examine and compare insider trading activities and the informativeness of insider trading under different regulation regimes. Our analysis not only expands the extensive literature that focuses mainly on insider trading in a single country or in a small group of countries, but also provides the first direct comparison of insider trading activities and their informativeness across countries. These comparisons allow us to assess the effects of insider trading regulations on insider trading activities and the informativeness of insider trades.

Second, our findings offer important insights on the opposing views regarding the effects of insider trading regulation on price informativeness and market efficiency. We present the first and direct evidence that insider trading regulation improves both the informativeness of insider trades and the efficiency of stock prices. The evidence provides support to the argument that insider trading regulation improves stock price efficiency. Several previous studies show that insider trading restrictions lead to greater information acquisition efforts (Bushman *et al.*, 2005) and that the first enforcement of insider trading laws improves stock price informativeness (Fernandes and Ferreira, 2009). Our results are consistent with the findings of the two studies, but we provide direct evidence of the mechanism of how insider trading regulation can improve the informativeness of stock prices. Specifically, we show that allowing insiders to freely exploit their information advantage over the investor public has substantial adverse effects that can easily overwhelm any informational benefits from insider trading. Such adverse effects not only lead to noisier and less informative stock prices, but also reduce the informativeness of insider trades (and hence their information advantage).

Our study thus fills the gap of existing findings on insider trading regulation and stock price efficiency in different countries. Bhattacharya *et al.* (2000) examine shares trading on the Bolsa Mexicana de Valores and find that share prices do not react to company news in the Mexico stock market. They argue that because insider trades may have already transmitted such information to the market, company announcements do not add new information. Such arguments implicitly assume that insider trades in unregulated markets are informative and that stock prices, if fully reflecting insider information, could be efficient even if they do not respond to company announcements. While our sample does not include Mexico, our evidence suggests that insider trades in Mexico may not convey much information because their stock prices may not fully respond to any corporate news, either through corporate announcements or insider trades.

The remainder of the paper is organized as follows. In the next section, we provide a brief discussion of the related literature. Section 3 describes the data, and Section 4 evaluates the informativeness of insider trades and the impact of insider trading regulation on insider trade informativeness. Section 5 employs a corporate event – corporate earnings announcements – to examine the impact of insider trading regulation on stock price efficiency, and the final section concludes.

2. Related Literature

Over the past few decades, the economics of insider trading has remained a highly controversial topic among securities authorities and academics. The main issue is whether insider trading is economically inefficient and hence, ought to be subject to regulation. Critics of insider trading regulation argue that without regulation, inside information will be efficiently allocated to investors who value the information the most, and that the benefit of more efficient prices is a more efficient allocation of resources (Coase, 1960; Manne, 1966). Carlton and Fischel (1983) further argue that increased price efficiency can reduce investor uncertainty and better protect corporation information. Subsequent theoretical models (such as Dye, 1984; Leland, 1992; Shin, 1996; Noe, 1997) also suggest that insider trading makes stock prices more responsive to changes in the market. In other words, unimpeded insider trading facilitates the incorporation of information into stock prices, thereby improving price informativeness.

Proponents of insider trading regulation, however, argue that under certain circumstances, the adverse effects of insider trading could lead to less efficient stock prices. Manove (1989) shows that insider trading increases trading costs of liquidity traders and, hence, discourages liquidity trading and decreases market liquidity. This liquidity discount can be incorporated into a firm's stock price, thereby increasing the firm's cost of capital. Fishman and Hagerty (1992) put forth two adverse effects of insider trading. First, insider trading discourages non-insiders from obtaining information and trading, and this reduces the number of informed investors in the market. Second, in the presence of better informed insiders, the information gets unevenly distributed across investors in the market. As a result, the market becomes less competitive and stock prices become less efficient.

It is worth pointing out that both the opponents and proponents of insider trading regulation hold the view that unrestricted insider trading is more informative than regulated insider trading. For the opponents, more informed insider trading leads to more efficient prices. For the proponents, the highly informed insider trading, through its adverse effects on other market participants, leads to less efficient prices.

There is an extensive empirical literature that examines the informational value of insider trading. Given the widely available U.S. insider trades data, many existing, especially earlier, studies focus on U.S. markets and find that insider trades are informative (Jaffe, 1974; Finnerty, 1976; Seyhun, 1988; Lakonishok and Lee, 2001; George and Seyhun, 2002; Brochet, 2010). Non-U.S. studies also reach the same conclusion for Canada (Baesel and Stein, 1979), the U.K. (Pope *et al.*, 1990), Hong Kong (Wong *et al.*, 2000), South Korea (Lee *et al.*, 2009; Cheon *et al.*, 2011), Germany (Betzer and Theissen, 2009), Switzerland (Zingg *et al.*, 2007), Australia (Hotson *et al.*, 2007), Thailand (Budsaratragoon *et al.*, 2012), the Netherlands (Cziraki *et al.*, 2014; Degryse *et al.*, 2014), and European countries (Fidrmuc *et al.*, 2012). But other studies find that insider purchases contain no informational value in Norway (Eckbo and Smith, 1998), Spain (Del Brio *et al.*, 2002), and Australia (Brown *et al.*, 2003).

These empirical studies are primarily based on a single country or a small group of countries within a region. The findings do not offer systematic evidence on the informativeness of insider trades across countries, and these studies do not attempt to compare and explain the differences in the informativeness of insider trades across the countries. Because these studies typically investigate insider trading under the same regulatory regime, they also do not address the core question of the debate on insider trading regulation, that is, whether or not insider trading regulation helps to improve stock price efficiency.

Several recent studies have examined some aspects of the effects of insider trading regulation on the financial market. For example, Bushman *et al.* (2005) show that restriction of insider trading leads to greater information acquisition efforts by financial analysts. Min (2010) concludes that the insider trading sanctions reduce insider trading on average, and result in larger noise trading on M&A-related news and rumors. Chung and Zhang (2010) find that American Depositary Receipts (ADR) from countries that have enforced insider trading laws have better market liquidity and lower information asymmetry than ADR from countries that have not enforced insider trading laws. Bhattacharya and Daouk (2002) find that the first legal prosecution of insider trading can help to lower a country's cost of equity, presumedly because of improved information efficiency. Studying the effects of the first enforcement of insider trading laws, Denis and Xu (2013) find similar results for executive compensation, and Chen *et al.* (2017) show similar effects for corporate investment. Fernandes and Ferreira (2009) examine the impact of first enforcement of insider trading laws on the informativeness of stock markets. They find that price informativeness is substantially improved after the first enforcement of insider trading laws in developed markets.

These recent studies provide some evidence of the potential effects of insider trading regulation on stock price efficiency. However, none of these studies examine the effects of insider trading regulation on insider trading activities and the informativeness of insider trades. Without such direct evidence, we cannot study the mechanism through which insider trading regulation affects stock prices and address the core question of the debate on insider trading regulation. The purpose of our study is to address these issues.

3. Data and Summary Information

3.1. Insider Transactions

Our global insider transactions data are obtained from Director Deals, a specialist global market data company that monitors and analyzes share transactions made by directors and top executives of firms. Director Deals gathers information of share transactions by insiders of about 40 000 firms from 56 countries globally. The source of its data comes from company announcements made public under disclosure regulations and from stock exchanges. For a given transaction, this dataset includes stock identifiers (ISIN and SEDOL), market capitalization at the time of the transaction in U.S. dollars, company information, the country where the trade took place, ticker symbol, personal information of the insiders (name, title, date of birth), transaction type (award, buy, sell, transfer, exercise, given away, etc.), transaction date, price and number of shares traded, total value of transaction (in British pounds, euros and U.S. dollars), and the date an insider trade was announced or reported.

Our sample focuses on insider transactions in the home country where the firm's headquarter is located and where the transaction occurred and was reported.[4] We exclude countries with fewer than five firms with reported insider transactions for the entire sample period, and also exclude one major developed market, Japan, where insider trades are not required to be reported by law. Furthermore, our analysis is restricted to open-market insider buys and sells as other types of transactions are more likely attributable to liquidity and portfolio diversification considerations (Ofek and Yermack, 2000; Carpenter and Remmers, 2001). As a result, our final sample consists of 44 countries with varying start years when information on insider transactions becomes available. In Director Deals, the U.K., Ireland, and the Netherlands have the longest sample period from 1999 to 2013, whereas most emerging markets (such as Brazil, Chile, Indonesia, and Pakistan) have data starting from 2013. As a result, our sample period is from 2007 to 2013.

Table 1 presents the sample period for each country. The table reports the number of unique firms with reported insider transactions, average annual number of transactions, average annual value of transactions (in U.S. dollars), and average annual number of shares traded. The number of unique firms with reported insider transactions varies from five in Czech Republic to 6501 in the U.S., and the total number of unique firms employed in this study is 24 135. The average annual

[4]These transactions include the vast majority of insider trades in the database.

Table 1 Insider trading activity, regulation, and enforcement around the world

This table provides by country, the market type (developed [DEV] or emerging [EMG]), start year of insider trades at Director Deals, number of unique firms that report insider trades, average annual number of insider trades, average value of trades in millions $, average annual trade value relative to market capitalization in %, the year the insider trading (IT) law was established, the year IT law was first enforced, and a dummy variable (Active Enforcement) that equals 1 if insider trading prosecution occurred during the sample period, and 0 otherwise.

					Insider trades

number of transactions ranges from 20 for Hungary to 45 558 for the U.S. For example, in Australia, the total number of insider trades is $3044 \times 6 = 18\ 264$ during the entire sample period. The average ratio of the annual total value of transactions relative to total market capitalization varies from 0.005% for Brazil to 1.723% for Greece.

3.2. Insider Trading Laws

Table 1 also reports the year in which insider trading laws came into existence in a country and the year of first insider trading prosecution under insider trading laws. Information on the enactment of insider trading laws is obtained from Bhattacharya and Daouk (2002). All countries in our sample have adopted insider trading laws starting from 1934 (the U.S.) to 1999 (Cyprus). Bhattacharya and Daouk (2002) also provide information on the first insider trading prosecution in a country up to 1998. We use the same source and supplement the first enforcement information for our sample of countries. The year that the initial prosecution under insider trading laws took place is between 1961 and 2012, and only two countries in the sample have not enforced their insider trading laws. With the exception of Egypt (2009) and Estonia (2012), the first enforcement of insider trading laws in most countries occurred much earlier than our sample period. Our analysis has found that the first-time enforcement variable exhibits no impact on the informativeness of insider trades and, hence, we do not report the results in the subsequent tables.

In this paper, we develop a new measure of insider trading regulation based on how rigorously and actively one country enforces insider trading laws. Even though most countries in our sample have had at least one insider trading prosecution (e.g. the initial prosecution), many countries do not pursue such cases rigorously. During our sample period of 2007–2013, there was not a single case of insider trading litigation in 15 countries in the sample.[5] We thus define a variable "Active Enforcement" to measure the extent to which a country enforces its insider trading regulation consistently and rigorously. "Active Enforcement" is a dummy variable that equals 1 if the country has a prosecution event under insider trading laws within the sample period, and 0 otherwise. We collect information on such prosecution events from three major data sources: (i) the market regulator's official announcements and direct communication with the regulatory authorities; (ii) news search; and (iii) the Capital IQ Key Development database. Capital IQ provides corporate events internationally, and we manually check the events that have a key word of insider(s) to ensure that the reported event is an insider trading prosecution event. The results are shown in Table 1. Among the 44 countries in our sample, 29 have recent enforcement of insider trading laws over the sample period, while 15 countries do not have any active enforcement events.

[5]The results remain qualitatively similar even if we construct our enforcement variable based on a 5-year period prior to 2007.

3.3. Other Variables

Our analysis includes several country-level variables relating to legal, institutional, and economic development characteristics of the sample of countries. These variables could affect insider trading regulation and the enforcements, or could potentially serve as substitutes for the more specific insider trading regulation enforcement variable we constructed above.

Legal Origin is a binary indicator that takes the value of 1 if the origin of the country's legal system is common law and 0 otherwise, and such information is from table II of La Porta *et al.* (1998). Anti-self-dealing is obtained from Djankov *et al.* (2008) and is a measure of investor protection against expropriation by corporate insiders.[6] The table also presents time-series averages of three law or regulation enforcement variables, namely the rule of law (Rule of Law), government effectiveness (Effectiveness), and regulatory quality (RegQuality), from 1999 to 2013. These three variables are obtained from the Worldwide Governance Indicators (WGI) project, 2014 Update. These aggregate indicators combine views and survey results and intend to measure governance quality at the country level. Rule of law reflects the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement and property rights. Government effectiveness reflects the quality of public services, the quality of the civil service, and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies. RegQuality reflects the ability of the government to formulate and implement policies and regulations. The value of all these variables ranges from -2.5 to 2.5. As shown in the table, Pakistan has the lowest governance indicators: -0.851 for Rule of Law, -0.574 for Effectiveness, and -0.636 for RegQuality. Finland, on the other hand, has the highest Rule of Law (1.946) and Effectiveness (2.152), and Singapore maintains the highest RegQuality of 1.927.

The sample of countries is divided into developed and developing countries based on World Bank classifications. We use the ratio of country-level stock market capitalization to annual GDP to measure the level of stock market development in a country. Our data source for the time-series annual GDP is the World Bank's World Development Indicators (WDI) database. The stock market development variable and the developed country status serve as additional control variables in our empirical analysis.

[6]The anti-self-dealing index was constructed to measure minority shareholder protection based on private enforcement mechanisms, such as disclosure and litigation, that govern a hypothetical self-dealing transaction. It does not cover insider trading. See Djankov *et al.* (2008) for detailed description of the construction of the index.

4. Regulation Enforcement and Insider Trading

In this section, we study insider trading activities across 44 countries and evaluate their informational contents. We first document insider trading profits of varying time horizons in the sample of countries and then examine whether insider trading regulation enforcement has any influence on both insider trading activities and the informativeness of insider trades around the world.

4.1. Insider Trading Profits

We obtain daily stock prices from Compustat Global and North America, and further supplement stock return information from DataStream to compute insider trading profits. Drawn from the existing literature, for each country, we measure insider trading profits for insider buys and sells, separately, and we compute the profits based on the cumulative returns of the traded stocks in excess of the country index return over 5, 10, 20, 30, 60, 90, and 120 days after insider transaction dates.[7] To conserve space, Table 2 reports the overall results on insider trading profits estimated over 5, 10, 20, 60, and 120 days after transaction dates by country.

As Table 2 indicates, average cumulative excess returns associated with insider buys are mainly positive and those related to insider sells are primarily negative. For example, the 5-day cumulative excess returns for insider buys are positive in 38 countries, and 29 of them are statistically significant at the 5% level. On the other hand, 32 of the 44 countries yield negative 5-day average cumulative excess returns for insider sells, and about half of these returns are statistically significant at the 5% level. For insider buys, average cumulative excess returns range from −0.759% in Luxembourg to 1.530% in Ireland, and for insider sells, they are between −0.954% in Hungary and 1.550% in the Czech Republic. Similar patterns are observed in cumulative returns computed over longer horizons up to 120 days. Insider profits are higher for most countries when measured over longer horizons, but they also vary vastly across the countries.

Our findings are broadly consistent with the results of most prior studies based on some of the individual countries, but they contradict the evidence shown in a few studies. For example, our findings of profitable insider purchases are consistent with the findings of numerous studies on insider purchases, such as Seyhun (1988), Lakonishok and Lee (2001), and Jeng *et al.* (2003) on U.S. firms, Baesel and Stein (1979) on Canadian firms, Pope *et al.* (1990) on U.K. firms, Wong *et al.* (2000) on Hong Kong firms, Betzer and Theissen (2009) on German firms, Zingg *et al.* (2007) on Swiss firms, Hotson *et al.* (2007) on Australian firms, Budsaratragoon *et al.* (2012) on Thai firms, and Degryse *et al.* (2014) on Dutch firms. Our finding is also in line with Del Brio *et al.* (2002) on Spanish firms; the authors find no profitability in insider purchases or sales in Spain.

[7]The reporting requirements of insider trading differ across countries. For our sample period, the majority of the countries require reporting within two days of transaction.

Table 2 Insider trading profits over 5–120 days from transaction dates

This table reports insider trading profits for insider buys (Buy) and sells (Sell), separately, over varying periods from the transaction dates. Insider trading profits are the average cumulative excess returns (i.e. the return of a stock in excess of its country-level index) over 5, 10, 20, 60, and 120 days after the insider transaction date. Insider trading profits are expressed in percentage with their statistical significance at the 5% level denoted by an *.

Our evidence differs from the findings of a few studies, such as Eckbo and Smith (1998) on Norwegian firms and Brown *et al.* (2003) on Australian firms. Using a similar methodology, Eckbo and Smith (1998) find insider sales but not purchases, are profitable, whereas our analysis delivers the opposite results. Eckbo and Smith's study is based on insider trades of stocks in 197 companies from 1985 to 1992, whereas ours looks at insider trades of 262 Norwegian stocks between 2007 and 2013. Brown *et al.* (2003) find that directors' sales, but not purchases, are profitable during the 1996–2000 period. On the contrary, our analysis shows that insider purchases are profitable over the 2007–2013 period.

In summary, the above results broadly suggest that insider trades, particularly insider buys, are informative in the global stock markets. Insiders exploit their information advantage and profit from their trades. There also seem to be substantial variations in the profits of insider trades across the countries, as well as over different time horizons. We next turn to the analysis on the determinants of the informativeness of insider trades by exploiting the different insider trading regulation enforcement regimes and the different institutional characteristics across our sample of 44 countries.

4.2. Active Enforcement and Insider Trading Profits

In this subsection, we investigate whether active enforcement of insider trading regulation influences insider trading activities and their informativeness as measured by insider trading profits over varying horizons. We also examine how insider trading regulation enforcement relates to the legal environments in a country and whether any enforcement effects on informativeness and insider trades are driven by country-specific characteristics and general regulatory environments.

In our analysis, we estimate the following multivariate panel regression with various combinations of country-specific variables that are described above.

$$\begin{aligned} IT\ Profits_{i,t} = {} & \beta_1 + \beta_2 Active\ Enforcement_{i,t} + \beta_3 Legal\ Origin_{i,t} \\ & + \beta_4 Rule\ of\ Law_{i,t} + \beta_5 Effectiveness_{i,t} + \beta_6 RegQuality_{i,t} \\ & + \beta_7 Anti - Self - Dealing_{i,t} + \beta_8 Stock\ Dev_{i,t} + \beta_9 Dev_{i,t} + \varepsilon_{i,t}, \end{aligned} \tag{1}$$

where IT Profits denote profits associated with insider transactions in year t. We first compute insider trading profits separately for insider buys and insider sells over different time horizons. For each country and each year, we then compute the average insider trading profits for buy and sell transactions for the different horizons. Active Enforcement is the indicator variable as defined earlier. In our discussion below, we use active enforcement and enforcement interchangeably if the context is clear. We include several legal environment variables in the analysis to see whether insider trading regulation enforcement plays any unique role in different legal environments. These legal environment variables are more broadly defined and they could encompass the effects of insider trading regulation enforcement; they are Rule of Law, Effectiveness, and RegQuality as defined in the previous section. Anti-Self-

Dealing is a proxy for investor protection against corporate insider self-dealing in business decisions. The correlations among three law and regulation variables are greater than 0.9. The high correlation is not surprising as the three variables substantially measure similar quality of a country's regulatory environment. Hence, in our subsequent analyses, our regression model only incorporates these variables one at a time.

Additionally, we include several broad country-level characteristics in our baseline model. Legal Origin equals 1 if a country has a common law origin, 0 otherwise. Stock Dev is defined as the ratio of a country's stock market capitalization to its annual GDP, and proxies for the level of stock market development. The countries in the sample are divided into developed and developing countries, and we include a developed country indicator (Dev) in the regressions. We control for year fixed effects and cluster standard errors at the country level.[8]

We estimate model (1) using insider trading profits measured over varying horizons as separate dependent variables. To conserve space, Table 3 reports results based on insider trading profits measured over 5, 10, 20, and 120 day intervals for insider buys and sells, separately. Our unreported results, based on other time horizons, are qualitatively similar to those reported in Table 3.

Several results emerge from the table. First, the results show strong evidence that informativeness of insider buys measured over both short (5-, 10-, 20-day) and long horizons (120-day) correlates highly with active enforcement of insider trading regulation. The coefficients of Active Enforcement are robustly significant across the model specifications in columns (1)–(9) and across the four panels spanning the different time horizons. In contrast, the results for insider trading profits based on sell transactions in columns (10)–(18) produce significantly weaker evidence of informativeness. For example, the Active Enforcement coefficients are significantly positive for buy transactions across varying horizons. In contrast, not all of the Active Enforcement coefficients associated with sell transactions are statistically significant. We find some significant, though weaker, results for insider sells for the short-horizon of 5 days. However, moving beyond the 5-day horizon, the significant insider-sell results disappear completely. The different results for buy and sell transactions are not surprising, given the well-documented evidence in the literature that insider buy transactions are informative while insider sell transactions are not. In general, the evidence reveals that active insider trading regulation enforcement is associated with more, not less, informative insider trading.

Second, the results show that other variables that measure the broad legal environments do not subsume the effects of insider trading regulation enforcement. Because of the high correlation among the three legal environments variables, we include them separately, along with Active Enforcement in the regressions. Rule of Law, Effectiveness, and RegQuality are significantly related to insider trading profits

[8]Our results remain materially unaffected when the standard errors are clustered at the year level.

Table 3 Insider trading regulation enforcement and insider trading profits

This table presents panel regressions of aggregate insider trading profits (IT Profits) on Active Enforcement and country-level control variables, as well as year-fixed effects for insider buys and sells, separately. IT profits are computed by first cumulating stock returns in excess of country-level indexes over *N* days and then taking an average of the profits within each year for each country. Active Enforcement is a dummy variable that equals 1 if there is an IT law prosecution event within the sample period of the countries in our sample, 0 otherwise. Legal Origin identifies the legal origin of the company law or commercial code of each country (common law or civil law). It equals 1 if the law origin of a country is common law and 0 otherwise. Rule of Law reflects perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement and property rights. Effectiveness reflects perceptions of the quality of public services, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies. RegQuality reflects perceptions of the ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development. The definition of these three variables are obtained from the *2014 Worldwide Governance Indicators*. Anti-Self-Dealing is a proxy for investor protection and is obtained from Djankov *et al.* (). Stock Dev is defined as the ratio of country-level stock market capitalization to GDP and is a proxy for stock market development. Dev dummy equals 1 if the country is developed, 0 otherwise. *t*-statistics, based on clustered standard errors at the country level, are reported in parentheses. Statistical significance is denoted by *, **, and *** at the 10%, 5%, and 1% levels, respectively.

in a small number of specifications for the short horizons, but neither of these variables substitutes the effects of Active Enforcement. Other broad measures of country characteristics, such as the Dev dummy and stock market development (Stock Dev), also do not materially alter the significance of the Active Enforcement effects. Our findings highlight the unique role of insider trading regulation and suggest that the main determinant of insider trading profits is the effectiveness of insider trading regulation and not the overall effectiveness of the legal system in a country.

We also examine the potential effects of insider trading regulation on overall insider trading activities. It is possible that a lax insider trading regulation could lead to rampant insider trading, thereby resulting in, on average, less informed insider trading. It is also possible that differences in the effectiveness of insider trading regulation may lead to differences in legal versus illegal insider trading and to differences in reported and unreported insider trading across the countries. We estimate regressions similar to those specified in model (1) with the dependent variable of insider trading activity, defined as insider buy or sell transactions in dollar value scaled by a firm's market capitalization. Regression results for insider buys and sells are presented separately in Table 4. We exclude the specifications with the two variables of Effectiveness and RegQuality from the table as these two variables are highly correlated with Rule of Law, and the results are qualitatively similar.

As shown in Table 4, insider trading regulation is not significantly related to reported insider trading activities. For both insider buys and sells, the coefficients of our main variable of interest, Active Enforcement, are not statistically significant across all 12 models. None of the other country characteristics are consistently and significantly associated with insider trading activities. The results suggest that there is no statistical difference between the level of insider trading activity in countries with and without active regulation enforcement. While the analysis here does not rule out the possibility that there could be systematic differences in insider trading reports, the evidence, and particularly our analysis on insider trading activity before corporate earnings announcements in the next section, indicates that such differences, if any, are unlikely to lead to systematic biases in our results.

To sum up, this section shows that total insider trading activities, based on the value of insider transactions to market capitalization, do not differ significantly across countries. But insider trades are more informative in countries that actively enforce insider trading laws. These results are surprising. If insiders could exploit less from their information advantage, they should earn greater profits in their trades, all things being equal. Opponents of insider trading regulation also stress that allowing insiders to freely use their information leads to more informative insider trading and consequently promotes market price efficiency. Our results contradict these views. There are a couple of possible explanations for the findings. First, with active enforcement of insider trading regulations, insiders will trade on private information only when the expected profit is large enough to outweigh the cost of potential legal enforcements by regulators. Second, our results may be driven by the fact that insiders in developing economies may trade on behalf of their children

Table 4 Insider trading regulation enforcement and aggregate insider trading activities

This table presents panel regressions of aggregate insider trade values on Active Enforcement and country-level control variables as well as year-fixed effects for insider buys and sells, separately. IT Value is computed by first summing up insider transaction values within each year scaled by country-level stock market capitalization. Active Enforcement is a dummy variable that equals 1 if there is an IT law prosecution event within the sample period of the countries in our sample, 0 otherwise. Legal Origin identifies the legal origin of the company law or commercial code of each country (common law or civil law). It equals 1 if the law origin of a country is common law and 0 otherwise. Rule of Law reflects perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement and property rights. The definition of Rule of Law is obtained from the *2014 Worldwide Governance Indicators*. Anti-Self-Dealing is a proxy for investor protection and is obtained from Djankov *et al.* (2008). Stock Dev is defined as the ratio of country-level stock market capitalization to GDP and is a proxy for stock market development. Dev dummy equals 1 if the country is developed, 0 otherwise. *t*-statistics, based on clustered standard errors at the country level, are reported in parentheses. Statistical significance is denoted by *, **, and *** at the 10%, 5%, and 1% levels, respectively.

(Berkman *et al.*, 2014) or through accounts insiders control on behalf of family, trusts, retirement accounts, and foundations (Goldie *et al.*, 2019), and such activity may not be reflected as insider trades. In the next section, we investigate how active insider trading regulation enforcement leads to more, not less, informative insider trading and more informative prices.

5. Regulation Enforcement and Insider Trading around Earnings Announcements

In the preceding section, we have established that informativeness of insider trades varies across countries with different insider trading regulation regimes. Specifically, insider trading informativeness is more pronounced in countries with active enforcement of insider trading laws. In this section, our research design focuses on insider trading activities around corporate earnings announcements to examine how insiders behave around earnings announcements across countries with varying degrees of enforcement in insider trading. This approach is in contrast to the recent work by DeFond *et al.* (2007), who find that earnings announcements are more informative in countries with higher earnings quality, stronger investor protection, or in countries that have implemented enforcement of their insider trading laws for the first time. Our analysis of insider trading around this important corporate event allows us to assess the effects of insider trading regulation on insider trading activities, the informativeness of insider trading, and how insider trading activities under different regulation regimes affect price efficiency.

5.1. Insider Trading Around Earnings Announcements

The global earnings announcement data are obtained from the I/B/E/S database, which provides extensive coverage on analyst recommendations and forecasts from brokerage firms across the world. I/B/E/S contains earnings announcement dates of firms covered by analysts, firm names, analyst earnings forecasts, and actual earnings.

We compute 10-, 20-, and 30-day insider buying and selling activities before and after earnings announcement dates, using information available from the I/B/E/S database. Due to data availability in the I/B/E/S database, we are only able to compute Pre-Buy or Pre-Sell ratios for 40 countries. For an N-day trading activity around earnings announcements, we calculate the Pre-Buy (Pre-Sell) ratio as follows. The Pre-Buy (Pre-Sell) ratio is the amount of insider buys (sells) over N days prior to an earnings announcement date divided by insider buys (sells) over N days before and N days after the announcement date. We measure insider buys (sells) based on the number of shares, or based on the share value traded. For example, the 10-day Pre-Buy ratio is the ratio of insider buy transactions in the 10-day period before earnings announcements to the sum of insider buy transactions in the 10-day period before and 10-day period after earnings announcements.

Table 5 reports Pre-Buy and Pre-Sell ratios over varying lengths of windows around earnings announcements and also highlights the Pre-Buy and Pre-Sell ratios

Table 5 Insider trading activities around earnings announcements

This table reports insider trading activities around earnings announcement dates by country. Pre-Buy (Pre-Sell) Ratios are computed over 10-, 20-, and 30-day insider buy (insider sell) activities surrounding earnings announcement dates (EA). For an *N*-day trading activity around earnings announcement dates, the Pre-Buy (Pre-Sell) Ratio is the insider buys (sells) over *N*-days prior to the announcement date divided by insider buys (sells) over *N* days before and *N* days after the announcement date. We measure insider buys (sells) based on the number of shares traded (Share), or on the share value traded (Value). * denotes a significant difference in insider buys (sells) between pre- and post-earnings announcement dates.

that are significantly different from 0.5 at the 5% level by using an asterisk. Results show that insiders tend to buy or sell less prior to than after earnings announcements. Across all countries, their Pre-Buy and Pre-Sell ratios are mostly lower than 0.5. Based on the ratios computed over a 10-day period, 35 of the Pre-Buy ratios are statistically significant, whereas 30 of the Pre-Sell ratios are statistically significant at the 5% level. The Pre-Buy ratio based on shares ranges from 0 (Hungary) to 0.445 (Greece), while the Pre-Sell ratio varies between 0 (Czech Republic, Ireland, and Luxembourg) and 0.598 (Hungary); these ratios are 0.072 and 0.165, respectively, for the U.S. Note that none of the Pre-Buy and Pre-Sell ratios of >0.5 is statistically significant at conventional levels.

The results on insider trading reveal that insider trading regulation has substantial effects on insider trading activities around earnings announcements. The lower trading activity prior to earnings announcements could possibly indicate the joint effects of general insider trading regulation, insider trading lockout periods before earnings announcement imposed at the country level, and/or corporate internal policies prohibiting any insider from trading prior to earnings announcements.[9] On average, such regulations or policies deter insiders from trading on any material information available in the earnings reports prior to the release of such information to the public. However, we do observe considerable insider trading activities, even during the short 10-day window before earnings announcements, in most of the countries. Also, insider trading activities vary substantially across the countries. Based on the 10-day results, insiders in Sweden and the U.K. rarely trade before earnings announcements (with ratios of 0.038 and 0.042, respectively), but insiders in Greece and the Philippines trade almost as much before earnings announcements as after (with ratios of 0.445 and 0.439, respectively).

We perform the following multivariate regression to examine whether insider trading behavior around earnings announcements is related to insider trading regulation enforcement.

$$Pre - Buy_{i,t}\ (or\ Pre - Sell_{i,t}) = \beta_1 + \beta_2 Active\ Enforcement_{i,t} + Control\ Variables + \varepsilon_{i,t}, \tag{2}$$

where Pre-Buy and Pre-Sell are country-year observations. Active Enforcement, together with the control variables, are defined earlier. In this multivariate regression, we also include year fixed effects and report adjusted standard errors clustered at the country level. Table 6 reports regression results using Pre-Buy and Pre-Sell ratios calculated over 10, 20, or 30 days around earnings announcement dates as dependent variables.

The multivariate regression results corroborate the univariate ones shown in Table 5. Corporate insiders tend to buy less before earnings announcements in countries that actively enforce their insider trading laws. Enforcement actions deter

[9]We formally test the issue of lockout periods, but they are not included in the paper. Unlike the active enforcement, the existence of lockout periods is not a determinant of insider trading before earnings announcements.

Table 6 Insider trading regulation enforcement and insider trading activities around earnings announcements

This table presents panel regressions of aggregate *N*-day insider trading activities around earnings announcements (Pre-Buy or Pre-Sell) on Active Enforcement and country-level control variables as well as year-fixed effects for insider buys and sells, separately. Pre-Buy is defined as insider buy ratio before earnings announcements and is computed by taking the ratio of the total number of insider buy (in shares) before an earnings announcement to the sum of the total number insider buy (in shares) before and after earnings announcements. Active Enforcement is a dummy variable that equals 1 if there is an insider trading prosecution under the laws during our sample period, 0 otherwise. Legal Origin identifies the legal origin of the company law or commercial code of each country (common law or civil law). It equals 1 if the law origin of a country is common law and 0 otherwise. Rule of Law reflects perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement and property rights. The definition of Rule of Law is obtained from the *2014 Worldwide Governance Indicators*. Anti-Self-Dealing is a proxy for investor protection and is obtained from Djankov *et al.* (2008). Stock Dev is defined as the ratio of country-level stock market capitalization to GDP and is a proxy for stock market development. Dev dummy equals 1 if the country is developed, 0 otherwise. The regression model is performed using 10-, 20-, and 30-day insider trading activities before earnings announcement for buy and sell, separately. *t*-statistics, based standard errors clustered at country level, are reported in parentheses. Statistical significance is denoted by *, **, and *** at the 10%, 5%, and 1% levels, respectively.

insiders from trading prior to earnings announcements. For example, the coefficient of Active Enforcement in columns (1)–(6) of Panel A is consistently negative and statistically significant at the 5% level, even after controlling for the country's legal origin, rule of law, anti-self-dealing, and stock market development. The Active Enforcement coefficient varies between −0.066 ($t = -2.18$) and −0.103 ($t = -2.43$). In contrast, for insider sells, almost all of the Active Enforcement coefficients are statistically insignificant, suggesting that insider trading regulation affects only insider buys but not sells. One possible explanation for the insider sell results is that in many countries insiders could schedule their transactions, mostly sell transactions, in advance and conduct transactions based on such schedules. These transactions are not affected by corporate events and are largely immune to concerns of illegal insider trading.

Furthermore, the variables, Legal Origin and Rule of Law, have a consistently negative impact on both Pre-Buy and Pre-Sell ratios computed over varying windows, and their coefficients are mainly statistically significant. Their negative effects on Pre-Buy suggest that in countries with strong investor protection and better law and order, insiders tend to buy significantly less before earnings announcements. We find similar results for anti-self-dealing regulations.

In summary, the results show that insiders from countries without rigorous enforcement of insider trading regulation are far more likely to exploit material corporate information in their trading decisions than insiders from countries with rigorous enforcement. Even though corporate earnings announcements are high profile events that are closely followed and observed by investors and regulators alike, the substantial differences in reported insider trading activities across the countries suggest that insiders in countries without active enforcement not only conduct but also disclose their trades before earnings announcements. The results further suggest that different reporting requirements across countries, if any, or non-reporting by insiders for sensitive trades are unlikely to systematically affect our findings in the paper.

5.2. Insider Trading and Price Reaction to Earnings News

The extant literature has shown that earnings announcements generate significant price reactions. Recent studies also find that market reactions to corporate news, including corporate earnings news, differ across markets (Bhattacharya *et al.*, 2000; DeFond *et al.*, 2007). We examine market price reactions to earnings announcements in our sample of countries and investigate the association between price reactions and insider trading regulations and between price reactions and insider trading activities before earnings announcements.

We compute three different measures of price reactions, namely the cumulative return difference, return difference standard deviation, and abnormal return variance. Following existing studies, we focus on the price reaction of the [−1, 1] event window, which is arguably less noisy. These three measures are defined as follows.

1 *Abnormal return variance*: The abnormal return variance is the stock return variance over the event window [−1, 1], scaled by stock return variance over the estimation window [−120, −21]. Stock return variance over the event window is the average of squared prediction errors from the market model during the event window [−1, 1], whereas the stock return variance over the estimation window is the variance of residuals from the market model estimated over the estimation period [−120, −21].
2 *Cumulative return difference*: The absolute value of the cumulative stock return in excess of the country index return over the event window [−1, 1].
3 *Return difference standard deviation*: Standard deviation of stock returns in excess of the country index return over the event window [−1, 1].

All the price reaction measures are computed first by taking an average of the variables for each firm and then averaging within each country.

Table 7 presents results of the three price reaction measures. These measures indicate that price reactions around earnings announcements vary widely across the sample of countries. The average price reaction is 2.317 for abnormal return variance, 6.758% for cumulative return difference, and 2.728% for return difference standard deviation. The abnormal return variance varies from 1.214 (Hungary) to 4.554 (U.K.), cumulative return difference ranges between 3.562% (Chile) and 11.430% (Indonesia), and return difference standard deviation is between 1.394% (Chile) and 5.746% (Indonesia). Similar to the findings of DeFond *et al.* (2007), our results suggest that developed countries such as the U.S. and U.K. have stronger price reactions, whereas emerging countries such as Chile and the Philippines have the weakest.

We now examine whether and how each price reaction measure is related to insider trading regulation and insider trading activities. We first regress price reactions on Active Enforcement, along with the control variables, and the results are shown in Table 8. We find a consistently positive relation between active insider trading regulation enforcement and market price reactions to earnings news. Independent of the price reaction measure employed, Active Enforcement has a positive and statistically significant effect on market price reaction. The coefficients on Active Enforcement are all positive and statistically significant mostly at the 5% level. These results are consistent with our earlier findings that active enforcement of insider trading laws enhances price informativeness. In countries that rigorously enforce insider trading regulation, corporate earnings announcements contain substantial information, and stock price reacts strongly to earnings news.

We next examine the link between insider trading activities and price reactions around earnings announcements. We have documented that insiders actively trade around earnings announcements. In countries without active regulation enforcement, insiders in fact trade actively before earnings announcements. A natural question to ask is whether such trading activities have any substantial influence on price

Table 7 Market price reactions to earnings announcements

This table reports price reaction around earnings announcements over the event window of [−1, 1] for the sample period from 2007 to 2013. Price reaction is measured in three ways: abnormal return variance, cumulative absolute return difference, and return difference standard deviation. Abnormal return variance is the stock return variance over the event window [−1, 1], scaled by the stock return variance over the estimation window [−120, −21]. Cumulative absolute return difference is computed by cumulating the absolute value of stock return in excess of country-level indexes over the event window [−1, 1]. Return difference standard deviation is defined as the standard deviation of stock return in excess of country-level indexes over the event window [−1, 1]. Stock return variance over the event window is the average of squared prediction errors from the market model during the event window [−1, 1]. The stock return variance over the estimation window is the variance of residuals from the market model estimated over the estimation period [−120, −21]. All the price reaction measures are computed first by taking an average of the measures for each firm and then average within each country. Cumulative absolute return differences and return difference standard deviation are expressed in percentage.

	Price reactions

reactions to earnings announcements. We therefore estimate the following regression model.

$$Price\,Reaction_{i,t} = \beta_0 + \beta_1 BuyS_{i,t}(or\,BuyV_{i,t}) + Control\,Variables + \varepsilon_{i,t}, \qquad (3)$$

where Price Reaction is again measured by the abnormal return variance, cumulative return difference, and standard deviation of return difference. BuyV (BuyS) is the ratio of the total dollar value (the number of shares) of insider buys before earnings announcement dates to the sum of the total dollar value (the number of shares) of insider buys before and after earnings announcement dates. Both the price reactions and insider trading variables are country-year averages. Our regression models focus on insider buys as a measure of insider trading intensity before earnings announcements in the regression, because insider buys are generally more informative and also, insider buy ratios before earnings announcements are closely related to insider trading regulation.

Table 9 provides evidence on the relation between insider trading activity around earnings announcement (over a 10-day window) and market price reaction to earnings news. The main variables of interest are BuyS in columns (1)–(6) and BuyV in columns (7)–(12) with varying combinations of control variables. We find that insider trading activities before earnings announcements significantly dampen market price reaction to earnings news. The coefficients of BuyS and BuyV are consistently negative and highly significant across different measures of price reactions. Unreported results based on insider trading activities over different event windows (20- and 30-day) show similar results. Stock prices on average react less to earnings

Table 8 Insider trading regulation enforcement and price reactions to earnings announcements

This table presents panel regressions of earnings announcement price reaction on insider trading Active Enforcement and country-level control variables as well as year-fixed effects. Price reaction is measured in three ways: abnormal return variance, cumulative absolute return difference, and return difference standard deviation. Abnormal return variance is the stock return variance over the event window [−1, 1], scaled by the stock return variance over the estimation window [−120, −21]. Cumulative absolute return difference is computed by cumulating the absolute value of stock return in excess of country-level index return over the event window [−1, 1]. Standard deviation of return difference is defined as the standard deviation of stock return in excess of country-level index return over the event window [−1, 1]. Stock return variance over the event window is the average of squared prediction errors from the market model during the event window [−1, 1]. The stock return variance over the estimation window is the variance of residuals from the market model estimated over the estimation period [−120, −21]. The price reaction measures are computed first by taking an average of the measures for each firm and then average within each country. Active Enforcement is a dummy variable that equals 1 if there is an insider trading prosecution under the laws during our sample period, 0 otherwise. Legal Origin identifies the legal origin of the company law or commercial code of each country (common law or civil law). It equals 1 if the law origin of a country is common law and 0 otherwise. Rule of Law reflects perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement and property rights. The definition of Rule of Law is obtained from the *2014 Worldwide Governance Indicators*. Anti-Self-Dealing is a proxy for investor protection and is obtained from Djankov *et al.* (2008). Stock Dev is defined as the ratio of country-level stock market capitalization to GDP and is a proxy for stock market development. Dev dummy equals 1 if the country is developed, 0 otherwise. *t*-statistics, based standard errors clustered at country level, are reported in parentheses. Statistical significance is denoted by *, **, and *** at the 10%, 5%, and 1% levels, respectively.

Table 9 Earnings announcement price reactions and insider trading activity

This table presents panel regressions of earnings announcement price reaction on insider buy activities 10 days before earnings announcement dates and country-level control variables as well as year-fixed effects. Price Reaction is measured in three ways: abnormal return variance, cumulative return difference, and standard deviation of return difference. BuyS is defined as the insider buy ratio before earnings announcement dates in shares and is computed by taking the ratio of the total number insider buy (in shares) before earnings announcement dates to the sum of the total number insider buy (in shares) before and after earnings announcement dates. BuyV is defined as insider buy ratio before earnings announcement dates in dollar value and is computed by taking the ratio of the total insider buy (in dollar value) before earnings announcement dates to the sum of the total insider buy (in dollar value) before and after earnings announcement dates. Legal Origin identifies the legal origin of the company law or commercial code of each country (common law or civil law). It equals 1 if the law origin of a country is common law and 0 otherwise. Rule of Law reflects perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement and property rights. The definition of Rule of Law is obtained from the *2014 Worldwide Governance Indicators*. Anti-Self-Dealing is a proxy for investor protection and is obtained from Djankov *et al.* (2008). Stock Dev is defined as the ratio of country-level stock market capitalization to GDP and is a proxy for stock market development. Dev dummy equals 1 if the country is developed, 0 otherwise. The regression model is performed using 10-day insider buying activities before earnings announcement dates. *t*-statistics, based standard errors clustered at country level, are reported in parentheses. Statistical significance is denoted by *, **, and *** at the 10%, 5%, and 1% levels, respectively.

news when insiders trade actively before earnings announcements. These findings are consistent with our earlier evidence documented above: enforcement of insider trading regulation affects insider trading activity before earnings announcements, and such enforcements are also strongly associated with price reactions to earnings news.

5.3. Regulation Enforcement, Insider Trading, and Price Efficiency

We now examine the potential mechanism through which insider trading regulation affects insider trading and price efficiency. Do insider trading activities before earnings announcements reduce stock price informativeness without advancing price discovery, or do insider trades help incorporate earnings-related information into stock prices prior to the announcements, thus reducing stock price reactions to earnings announcements? In the former case, insider trades lead to less informative prices, as the trades themselves add little information to the market. In the latter, insider trades could affect when and what information gets impounded into stock prices, but may not affect the overall stock price efficiency.

In Table 10, we examine and compare gains associated with insider buys 10 days before and 10 days after earnings announcements in countries with and without active regulation enforcement. We use two variables to measure pre-announcement insider trading gains: insider trading gains over the period up to 1 day *before* earnings announcement and insider trading gains over the period up to 1 day *after* earnings announcement. The first variable measures the informativeness of insider trading excluding the public announcement of earnings information, and the second variable measures the informativeness of insider trading including the earnings information. For example, if an insider trade occurs on day -10 (where day 0 is the earnings announcement day), we compute the insider's trading profits from day -9 to day -2 by summing up the stock return in excess of the country return from day -9 to day -2. Then, we take the average of the profits of all insider transactions that occur within each year for each country. This represents the insider trading profits excluding earnings announcement returns. For profits including earnings announcement returns, we would compute the insider's trading profits from day -9 to day 1 by summing up the stock return in excess of the country return from day -9 to day 1. If an insider trade occurs on day 1, we compute the insider's trading profits from day 2 to day 11 by summing up the stock return in excess of the country return during this period, and then compute the average of the profits of all insider transactions that occur within each year for each country. All insider trading gains after earnings announcements are measured over the 10-day period after the transaction. We employ a "Before" dummy to denote insider trading gains from pre-announcement trading activities. The first six models use insider trading gains excluding earnings announcement abnormal returns. Such gains measure insider trading profits before earnings information becomes public.

Table 10 Enforcement and insider transaction profits around earnings announcements

This table presents panel regressions of insider trading profits for trading activities 10 days before and 10 days after earnings announcements on Active Enforcement and country-level control variables as well as year-fixed effects for insider buys including and excluding earnings announcement profits, separately. Insider trading profits (including earnings announcement profits, Include EA Profits) are computed by first cumulating stock returns of each insider trading transaction that occurs between 10 days before and 10 days after earnings announcements in excess of country-level indexes, including the return on the day of the earnings announcement, and then taking an average of the profits within each year for each country. Insider trading profits (excluding earnings announcement profits, Exclude EA Profits) are defined in the same way, with the exception of excluding the return on the earnings announcement day. Active Enforcement is a dummy variable that equals 1 if there is an insider trading prosecution under the laws during our sample period, 0 otherwise. Before dummy equals 1 if the profit is before earnings announcements, 0 otherwise. The regression model is performed using 10-day insider trading activities before earnings announcements. *t*-statistics, based standard errors clustered at country level, are reported in parentheses. Statistical significance is denoted by *, **, and *** at the 10%, 5%, and 1% levels, respectively.

The results show that independent of whether or not we include the 3-day stock returns around earnings announcements, insider trading around earnings announcements is more informative in countries with active enforcement of insider trading regulation than in those without. Based on insider trading gains that include earnings announcement abnormal returns, the interaction of Active Enforcement and “Before” dummies is positive and mainly significant at the 10% level. The implication is that in countries where insider trading regulation is actively enforced, insider trades are more informative before earnings announcements and the insider information is reflected in the stock prices during earnings announcements. However, in countries with lax regulatory environments, active insider trading before earnings announcements reduces stock price informativeness without advancing earnings news or helping to incorporate earnings information into stock prices.

To summarize, our results suggest that active enforcement of insider trading regulations leads to more informative insider trading and greater stock price efficiency. Even though insiders from countries with weak insider trading regulations could exploit their information advantage, such as corporate earnings news, in their trades, market reactions to corporate news are weaker, resulting in noisier stock prices. At the same time, the noisier stock prices reduce the potential information advantage of insiders and hence, lower the informativeness of insider trades.

6. Conclusion

This study offers direct evidence that active insider trading enforcement engenders more, and not less, informative insider trades. These findings are in stark contrast to the arguments that insider trading regulation reduces the informativeness of insider trades and hinders price efficiency. These results remain robust after controlling for various country-level institutional characteristics that include the rule of law and the general effectiveness of law enforcement. Our analysis of insider trading activities around corporate earnings announcements provides insights into why active insider trading enforcement results in more informative insider trades and more efficient stock prices. In countries with active enforcement of insider trading regulations (i) insiders trade significantly less prior to corporate earnings announcements over 10- to 30-day intervals, (ii) insiders tend to refrain from trading on material non-public information, and (iii) stock price reactions to corporate earnings announcements are stronger. In countries without active insider trading enforcement, insiders trade more before earnings announcements, but their trades do not help to incorporate earnings-related information into stock prices, and stock prices also react less to earnings announcements.

Perhaps our most striking finding is that enforcement of insider trading regulation leads to both more informative insider trading and greater stock price efficiency. Opponents of insider trading regulation argue that unrestricted insider trading leads to more informed trading and to more efficient prices; however, our results show no support for this argument. While proponents of insider trading regulation contend that unrestricted insider trading could lead to less informationally efficient stock prices, they also tend to hold the view that such insider trades can be highly informative. Our results show that less informative prices render less informative insider trades. The evidence suggests that informativeness of insider trades and stock price efficiency are simultaneously determined, parallel results.

Our research has additional public policy implications. Enforcement of insider trading laws, not the establishment of the insider trading laws, facilitates stock market efficiency and promotes informative insider trading. Bhattacharya and Daouk (2002) and several subsequent studies find that initial enforcement of insider trading regulation could significantly affect price efficiency. Our study shows that continuous and active enforcement of insider trading regulation could help to achieve regulators' primary goal of monitoring insider trading activities and improving stock market efficiency.

Working capital management and firm's valuation, profitability and risk

Evidence from a developing market

Ben Le
College of Business and Public Management, Kean University, Union, New Jersey, USA

Received 11 January 2018
Revised 22 May 2018
Accepted 14 June 2018

Abstract

Purpose – The purpose of this paper is to examine the effects of working capital management on firm valuation, profitability and risk.

Design/methodology/approach – The paper uses a panel data set of 497 firms covering the period 2007 to 2016. The authors test the effects of working capital management on firm valuation, profitability and risk using the panel data methodology that includes firm and year fixed effects regressions.

Findings – The authors find a significantly negative relationship between net working capital (NWC) and firm valuation, profitability and risk. The results suggest that, in managing working capital, firm managers must make a trade-off between their objectives for profitability and risk control. Working-capital management is of particular importance in firms with less access to capital; it is also important when firms are expanding their investments during periods of economic recovery.

Originality/value – This paper contributes to the literature in several ways. First, to my knowledge, it provides the most comprehensive investigation, to date, on the relationship between working capital management and firm valuation, profitability and risk in an emerging market. Second, this study documents the existence of an optimal level of NWC in an emerging market. Third, firm performance, as measured in both market and accounting value, can be improved with efficient working capital management. Finally, the study includes the impact of the business cycle in an analysis of the effects of working capital management on firm performance.

1. Introduction

The literature on working-capital management (WCM) has found that efficient management can enhance profitability and increase firm value. Shin and Soenen (1998) are one of many studies that have found a negative relationship between the cash conversion cycle (CCC) and firm profitability. The results imply that a reduction in the CCC is directly associated with an increase in profitability. Havoutis (2003) argues that firms have control over their WCM and that, with efficient control, they can increase their economic value. One measure of firm value is the total present value of its expected future free cash flows (FCF). Net working capital (NWC) is a determinant of FCF. Berk *et al.* (2009) note that efficient WCM can increase FCF, and consequently enhance the value of a firm. Few studies investigate the relationship between NWC and firm value. Wasiuzzaman (2015) documents a negative relationship between the level of NWC and firm value for firms in Malaysian markets. Aktas *et al.* (2015) find a negative relationship between firm value and excess NWC in firms with abnormally high levels of NWC in US markets. However, this relationship is positive in firms with low levels of NWC.

Jensen Michael (2001) notes that a firm's goal is to maximize its total market value, and that it is impossible for a firm to have multiple goals. Maximizing a firm's value is not always the same as maximizing its profits. Unfortunately, current studies only test the influence of WCM on either a firm's profitability or its value by using separate data sets.

There is a lack of research that examines the effects of WCM on firm profitability and firm valuation, using the same data set. Further, few studies address the effect of a change in NWC on firm risk.

The results of existing studies imply that a firm can increase its profitability by reducing its CCC. A lower CCC is usually associated with a lower level of NWC. This paper attempts to answer the following questions: in a market, if the CCC is negatively related to profitability, then will a decrease in NWC be associated with a higher firm value? What is the effect on firm risk of reducing NWC?

On a global equity-investment perspective, emerging markets have been attracting considerable attention from international investors. This paper aims to extend the research of WCM on an emerging economy and provide to the literature new evidence on the impact of WCM on firm value. In particular, this study uses a panel data set from stock markets in Vietnam over the period 2007 to 2016 to investigate the effects of WCM on firms' value, profitability and risk over the most recent decade for which data is available. Vietnamese stock exchanges present a unique opportunity for a case study on WCM. Over this period, current assets represent 62.06 percent of firms' total assets and current liabilities represent 80.78 percent of their total liabilities; these values, in turn, are equal 98.00 percent of their total equity. Vietnamese firms are heavily dependent on short-term financing and short-term assets account for the major portion of these firms' balance sheets. Hence, appropriate WCM and financing policies are tools a firm can use to increase their valuation.

Campos and Kinoshita (2003) note that former communist countries provide an extremely valuable but are underutilised opportunity for research. As a former communist country, Vietnam opened its economy in the early 1990s, which was a decade of market liberalization globally. The country now has two stock exchanges: the Ho Chi Minh Stock Exchange, which was established in 2000, and the Hanoi Stock Exchange, which was launched in 2005. Demigurc-Kunt and Maksimovic (2002) find that the development of a country's legal system as it pertains to capital markets predicts its firms' access to external capital: "[T]he development of securities markets is related more to the availability of long-term financing, whereas the development of the banking sector is related more to the availability of short-term financing." Vietnam's securities markets have only recently been established. The country's firms have limited alternative sources of external capital, a situation that is consistent with their very high percentages of short-term liability to total liability.

In November 2006, Vietnam joined the World Trade Organization. Since 2007, the country's firms have become more integrated into global markets. The market-value-weighted foreign ownership of Vietnamese listed firms was 27.56 percent, on average, during the period 2007 to 2016, the US ranking second among the countries investing in Vietnamese stock markets[1]. Foreign investment provides an important source of capital to domestic firms. Their integration into global markets provides benefits but also pushes these firms' management to improve their firms' performance. In addition to foreign investors providing financing, the government also finances several Vietnamese listed firms. During the period 2007 to 2016, the government-owned 50.00 percent or more of the total shares outstanding of over 36 percent of all listed firms, accounting for an important source of these firms' capital.

This paper contributes to the WCM literature in several ways. First, to my knowledge, it provides the most comprehensive investigation, to date, on an emerging market and the relationship between working capital management and firm performance as measured by firm valuation, profitability and risk. Second, this study documents the existence of an optimal level of NWC in an emerging market. This finding is comparable with Baños-Caballero *et al.* (2014) and Aktas *et al.* (2015), who documented the existence of optimal working-capital-investment levels in UK and US markets, respectively. However, this paper uses different research methods.

First, whereas Aktas *et al.* (2015) use abnormal returns as a measure of firm value, this paper uses the market-to-book ratio; it also tests for the effects of NWC on firm profitability. Second, whereas Baños-Caballero *et al.* (2014) utilize a non-linear model to examine the effects of the net trade cycle on a firm's market-to-book ratio, this paper uses a linear model that includes firm and year fixed effects in all of the regression analyses.

Third, this paper indicates that firm performance, as measured in both market and accounting value, can be improved with efficient WCM. Finally, the study includes the impact of the business cycle in an analysis of the effects of WCM on firm performance.

The remainder of the paper is organized as follows: Section 2 reviews the existing literature. Section 3 includes the models and hypotheses, Section 4 provides a description of the data. Section 5 discusses the results and Section 6 concludes.

2. Literature review

WCM is important to a firm's overall management. The level of NWC influences a firm's profitability and value; it is determined by the inventory level, the value of accounts receivable and accounts payable. Blinder and Maccini (1991), Fazzari and Petersen (1993) and Corsten and Gruen (2004), among others, argue that a high inventory level (thus, a high NWC) increases profits by lowering supply costs and the potential loss of sales due to stock outages; it also provides a hedge against variations in the prices of inputs. With respect to the management of accounts receivable, on the one hand, Brennan *et al.* (1988), Long *et al.* (1993) and Summers and Wilson (2002), among others, propose that granting credit to customers and, thus, increasing the level of accounts receivable can foster long-term relationships with customers, which can potentially increase sales and profits. On the other hand, Kieschnick *et al.* (2013) argue that an increase in NWC requires additional financing. Firms that hold too much working capital may incur high-interest expenses and potentially the risk of bankruptcy (see, Aktas *et al.*, 2015). Eljelly (2004) includes the concept of an efficient WCM that requires a current asset level that is sufficient to meet short-term obligations but also to avoid excessive investment in current assets. Berk *et al.* (2009) imply that efficient WCM redeploys FCF or underutilised resources to pursue higher-value projects so as to create value for the firm.

The effects of the CCC, and its components, on profitability are well documented. Most studies find a negative relationship between CCC and the profitability of firms around the world, for example, for the USA (see Jose *et al.*, 1996; and Shin and Soenen, 1998); for Japan and Taiwan (see Wang,2002); for Greece (see Lazaridis and Tryfonidis, 2006); for Spain, during the period 1996 to 2002 (see García-Teruel and Martínez-Solano, 2007); for Pakistan (see Raheman and Nasr, 2007); for Turkey (see Karaduman *et al.*, 2010; and for Germany, see (Wöhrmann *et al.*, 2012). Deloof (2003) finds a negative relationship between CCC and profitability in Belgian markets; however, these results are insignificant. He also finds a negative impact on profitability of days sales outstanding (DSO), days sales inventory (DSI), and days payable outstanding (DPO). However, Baños-Caballero *et al.* (2012) use data on Spanish firms for the period 2002 to 2007 and Baños-Caballero *et al.* (2014) use data on UK firms for the period 2001 to 2007 and find a concave relationship between CCC and profitability and argue that there exits an optimal level of NWC that maximizes a firm's value.

Cash holdings is a component of NWC. Existing studies provide different effects of cash holdings on firm value. On the one hand, Luo and Hachiya (2005), Pinkowitz *et al.* (2006), Kalcheva and Lins (2007), Harford *et al.* (2008) and Lee and Lee (2009) find a negative relationship between cash holdings and firm value. On the other hand, Faulkender and Wang (2006), Bates *et al.* (2009) and Isshaq *et al.* (2009) find positive results from cash holdings on firm value. Martinez-Sola *et al.* (2013) find a concave relationship between cash holdings and firm value, and verify the existence of an optimum level of cash holdings.

Although there are numerous studies on the effects of cash holdings on firm value, there is little research related to the effects of NWC on firm value. Wang (2002) finds that, in the Japanese and Taiwanese markets, higher-valued firms invest less in NWC than lower-valued firms. Wasiuzzaman (2015) finds that a reduction in NWC increases firm value in Malaysian markets. In US markets, using a model similar to that in Faulkender and Wang (2006), Kieschnick *et al.* (2013), Wasiuzzaman finds that the incremental dollar held in cash is worth more than the incremental dollar invested in NWC. For US markets, Aktas *et al.* (2015) show that, among firms that underinvest in working capital, there is a positive relationship between the level of NWC and stock performance. However, for firms with abnormally high levels of NWC, excess NWC is negatively related to stock performance.

3. Model and hypotheses

Firm value can be estimated by discounting its expected future FCF. Brigham *et al.* (2015) note that firm value can be estimated by discounting the FCF the firm generates, as follows:

$$V_0 = \sum_{t=1}^{\infty} \frac{\mathrm{FCF}_t}{(1+\mathrm{WACC})^t}, \tag{1}$$

where $\mathrm{FCF}_t = \mathrm{EBITDA}_t - \mathrm{CAPEX}_t - \Delta\mathrm{NOWC}_t$. WACC is the weighted average cost of capital. CAPEX is the total cost of long-term assets and ΔNOWC is the change in net operating working capital. Wasiuzzaman (2015) notes that "NWC is an important component of free cash flow." Existing studies typically measure firm value, using either the market-to-book ratio (Fama and French, 1998, among others) or the stock's excess return (Faulkender and Wang, 2006, among others). In this paper, I modify the models used by Fama and French (1998) and Wasiuzzaman (2015), and use the market-to-book ratio as the dependent variable that measures firm valuation as follows:

$$\begin{aligned} \mathrm{MTB}_{i,t} = {} & \beta_0 + \beta_1 \mathrm{CAPEX}_{i,t} + \beta_2 \mathrm{INTEREST}_{i,t} + \beta_3 \mathrm{CASHD}_{i,t} + \beta_4 \mathrm{GROWTH}_{i,t} \\ & + \beta_5 \mathrm{CFOSALES}_{i,t} + \beta_6 \text{ LOG (SIZE)}_{i,t} + \beta_7 \mathrm{WC}_{i,t} + \beta_8 fe_{i,t} + \varepsilon_{i,t}, \end{aligned} \tag{2}$$

where MTB is the market-to-book ratio and WC is the interest variable that is either NWC = (accounts receivable + inventory – accounts payable)/total book assets or CCC. Table I presents the descriptions and calculations of the variables.

In Equation (2), the MTB is the ratio between the year-end market value per share and the book value per share. A firm's goal is to maximize its market value. In this model, I focus on the effects of a change in NWC on a firm's value. The CAPEX is capital expenditure scaled by total book assets; INTEREST represents the interest expenses a firm incurs during a year, scaled by total book assets; CASHD is the total cash dividends paid out during a year, scaled by total book assets; GROWTH represents the growth rate of sales; CFOSALES is the operating cash flow, divided by sales for the year; SIZE is the total book value of assets that controls for firm size. Cash dividends, cash flows from operations, and sales growth rate represent the firm's generated cash flows. In all of the regressions, I include $fe_{i,t}$, which represents firm and year fixed effects, to control for the time-invariant firm characteristics and to reduce issues related to missing variables (see also, Aktas *et al.*, 2015). The focus of my model is the effects of NWC and CCC on firm value.

In order to examine the effects of WCM on a firm's profitability, this paper uses the following model:

$$\begin{aligned} \mathrm{ROIC}_{i,t} = {} & \beta_0 + \beta_1 \mathrm{CAPEX}_{i,t} + \beta_2 \mathrm{GROWTH}_{i,t} + \beta_3 \mathrm{LEV}_{i,t} + \beta_4 \text{ LOG (SALES)}_{i,t} \\ & + \beta_5 \mathrm{VOL}_{i,t} + \beta_6 \mathrm{WC}_{i,t} + \beta_7 fe_{i,t} + \varepsilon_{i,t} \end{aligned} \tag{3}$$

Variable	Description	Unit	n	Mean	SD
AGE	The number of months from IPO to date	Months	3,358	57.905	36.291
CAPEX	Capital expenditure. Total amount spent for purchasing capital assets	Percent	3,358	6.047	7.891
CASHD	Total cash dividend paid during the year scaled by total book assets	Percent	3,358	2.574	4.385
CCC	Cash conversion cycle = DSO+DSI−DPO	Days	3.358	143.94	138.08
DPO	Days payable outstanding = (Accounts payable × 365)/cost of goods sold	Days	3,358	52.91	50.04
DSI	Days sales inventory = (Inventory × 365)/ cost of goods sold	Days	3,358	108.935	103.088
DSO	Days sales outstanding = (Accounts receivable × 365)/sales	Days	3,358	87.911	89.404
DUMMY	Equal 1 for period 2007–2012 (financial crisis period), 0 otherwise		3,358	0.558	0.497
CFOSALES	Net operating cash flows scaled by sales	Percent	3,358	7.98	14.596
GOV	Government ownership = Percentage of shares owned by the government	Percent	3,358	28.77	23.48
GROWTH	Growth rate of sales = (Current year sales−previous year sales) × 100/previous year sales	Percent	3,358	13.338	36.713
INTEREST	Total interest expenses of the year scaled by total book assets	Percent	3,340	2.2605	2.1098
LEV	Leverage = (Debt/equity) × 100	Percent	3,358	98.015	149.88
MTB	Market to Book ratio = Market value/Book value per share		3,358	1.175	1.32
NWC	Net working capital scaled by total book assets. Net working capital = accounts receivable + inventories − accounts payable	Percent	3,358	32.27	19.26
OWN[a]	Percentage of shares owned by foreigners	Percent	3,358	9.458	13.047
ROIC	Return on invested capital = (Net income + interest expenses) × 100/(total capital + short term debt + current portion of long term debt)	Percent	3,358	11.487	9.545
SALES	Total revenue of a year	VND billion	3,358	1,416.14	3,370.96
SIZE	Firm size, equal total book assets	VND billion	3,358	1,574	5,604
VOL	Stock return volatility = Standard deviation of stock return	Percent	3,079	11.984	5.775

Notes: This table summarizes the statistics all of the variables used in this paper. The sample includes non-financial firms from DataStream over a decade from 2007 to 2016. The data are obtained from DataStream. The data are winsorised at the 1 percent level for the following variables: NWC, CCC, DSO, DSI and DPO. The final data set includes 497 unique firms over 10 years, with a total of 3,358 firm-year observations, except for interest expenses (3340 observations) and stock return volatility (3,079 observations). [a]This is the equally weighted average foreign ownership. The market capitalization value weighted average of foreign ownership is 27.56 percent. The evidence shows that foreigners invest more in firms with large market capitalization

Table I. Summary statistics

In Equation (3), the dependent variable is the return on invested capital (ROIC); WC is the focused variable, that is, CCC, NWC or the components of CCC, including DSO, DSI and DPO (where CCC = DSO + DSI −DPO). Shin and Soenen (1998) and Baños-Caballero *et al.* (2014), among others, use CCC to test the effects of WCM on firm profitability. Stock-return volatility (VOL) is utilized to control for firm risk. Following Deloof (2003), I use total revenue (SALES) to control for firm size. Table I provides descriptions and calculations of these variables:

H1. A lower NWC and CCC positively affect firm performance.

Firm performance is measured using either market value (in this paper, I use market-to-book ratio) or accounting value (profitability). I expect that a reduction in NWC or CCC is associated with an increase in MTB and ROIC. WCM is related to a firm's management of its FCF, inventory and accounts payable; thus, WCM affects firm value and profitability. A higher FCF increases firm value. Current research has found significant effects of CCC on firm profitability and also effects of NWC on firm value. In markets in Vietnam, I also expect that CCC and NWC have significant influences on firm profitability and value.

There is a direct relationship between NWC and CCC. Controlling for other information, an increase in inventory and accounts receivable, and/or a decrease in accounts payable are associated with an increase in DSI and DSO and a decrease in DPO. Consequently, both NWC and CCC increase. Suppose a firm has excessive NWC; that is, levels of inventory and accounts receivable are higher and/or accounts payable are lower than necessary. In either case, both NWC and CCC are too high. We may expect a negative relationship between the level of NWC and firm value and a negative association between firm profitability and CCC. A firm can improve its performance by reducing the level of its NWC level and its CCC:

H2. For firms with better access to capital, firm value is less sensitive to changes in NWC.

Wasiuzzaman (2015) uses firm size as a proxy for constraints on financing. He argues that large firms are more reputable and, therefore, have better access to capital markets than small firms. In this paper, I utilize the total percentage of government and foreign ownership (GOVOWN = foreign ownership + government ownership) of a firm as a proxy for ease of access to sources of financing. Sun and Tong (2003) find for China and Le *et al.* (2018) find for Vietnam that the cost of borrowing is lower for state-owned enterprises (SOEs) (either implicit or explicit cost) than for other firms because SOEs carry government guarantees. Blenman and Le (2014) find that foreigners that invest in Vietnam target a long-term horizon, thereby helping provide financing to the firms they invest in. However, Teach notes the negative effect of easy capital access; he coins the term barely working: "The availability of cheap debt has reduced companies' incentive to improve working-capital management" (2015). Hence, I expect firm value is less sensitive to changes in NWC in firms that have higher GOVOWN.

The following model is used to test the effects of NWC on firm risk:

$$\mathrm{VOL}_{i,t} = \beta_0+\beta_1\ \mathrm{LOG\ (SIZE)}_{i,t}+\beta_2\mathrm{MTB}_{i,t}+\beta_3\ \mathrm{LOG\ (AGE)}_{i,t}+\beta_4\mathrm{NWC}_{i,t}+\beta_5\mathrm{OWN}_{i,t}$$
$$+\beta_6\mathrm{GROWTH}_{i,t}+\beta_7\mathrm{LEV}_{i,t}+\beta_8\mathrm{DUMMY}+\beta_9 fe_{i,t}+\varepsilon_{i,t}, \quad (4)$$

In Equation (4), the volatility of daily stock returns (VOL) is the dependent variable; AGE is the number of months, to date, since a firm's IPO; OWN is the percentage total ownership of foreign investors at year end; NWC is scaled by the book value of total assets. Table I provides descriptions and calculations of the variables:

H3. The relationship between stock-return volatility and the level of NWC is negative.

As discussed in studies, a high inventory level can reduce potential stock outages, provide protection against input price variations and foster long-term relationships with customers by granting them credit (Blinder and Maccini, 1991; Fazzari and Petersen, 1993; Corsten and Gruen, 2004; Brennan *et al.*, 1988; Long *et al.*, 1993; Summers and Wilson; 2002). I also expect a negative relationship between volatility and firm size and age.

In the above equations, the subscript i means firm i, and t means year t.

4. Description of the data

The sample data were obtained from DataStream, which consists of financial information for the Vietnamese companies listed on the Ho Chi Minh and the Hanoi stock exchanges. The Hanoi Stock Exchange launched in 2005 with only seven listed stocks; its number of stocks increased to 105, in 2007. The sample data cover the period 2007 to 2016. Financial institutions are excluded from the sample. The data are winsorised at the 1.00 percent level for the following variables: NWC, CCC, DSO, DSI and DPO. The final data set includes 497 unique firms, over 10 years, with a total of 3,358 firm-year observations, except for interest expenses (3,340 observations) and stock-return volatility (3,079 observations).

Table I summarizes the statistics of all of the variables used in the paper. I refer to the period 2007 to 2012 as it was a period of financial crisis and stock markets in Vietnam saw prices drop over these six years. The stock market then started to recover in 2013, so I refer to 2013 to 2016 as the recovery period. The ratio of NWC to sales, on average, is 37.15, 35.33 and 39.45 percent, for the full sample, the crisis period, and the recovery period, respectively. Among the 3,358 observations, 3,279 firm-years show positive NWCs, and 79 firm-years show negative NWCs. NWC over sales amounted to 38.16 and −4.54 percent for the positive and negative NWC firm-years, respectively. In comparison with total assets, over the period 2007 to 2016, on average, NWC was 32.37 percent. The average NWC was 33.18 percent for positive NWC firms, and −5.77 percent for negative NWC firms.

Figure 1 presents the variations of the CCC and its components, from 2007 to 2016. On average, DSI and DSO are significantly higher than DPO, causing CCC to almost triple DPO. Among the three components of CCC, DSI is the longest. The CCC tends to increase from 2007 to 2013 and then decrease in 2013.

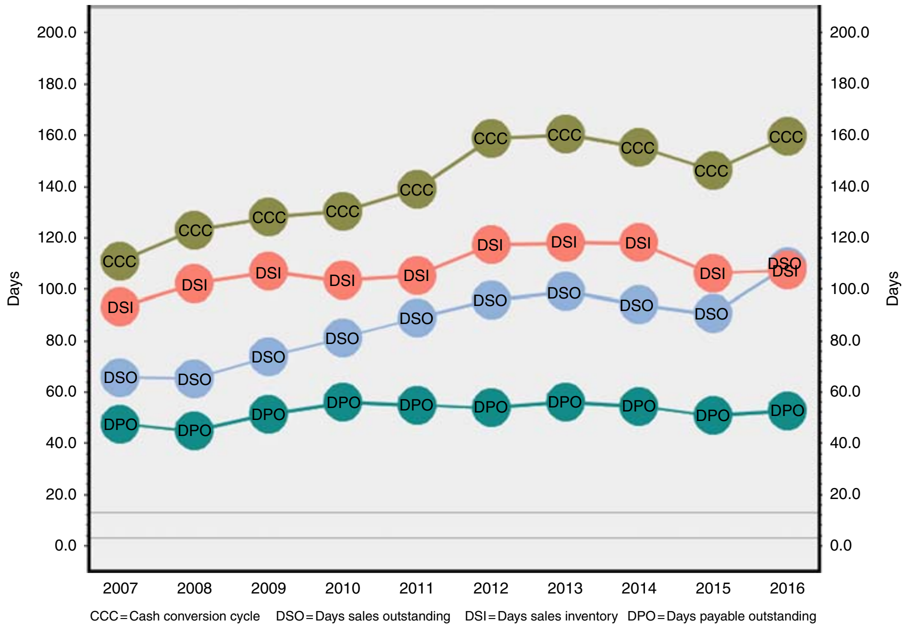

Figure 1. Cash Conversion Cycle and Its Components 2007–2016

Notes: This figure presents yearly average CCC, DSO, DSI and DPO. The sample includes 497 unique non-financial firms with 3,358 firm-year observations, obtained from DataStream over a decade from 2007 to 2016. The descriptions of CCC, DSO, DSI and DPO are summarised in Table I

5. Regression analysis

5.1 The effects of WCM on firm profitability and value

Table II reports the effects of NWC, CCC and other factors on the firm valuation for the period 2007 to 2016. Firm and year fixed effects are included in all models. The market-to-book ratio at year end is the dependent variable. The evidence shows that CASHD, GROWTH, CFOSALES and CAPEX have positive impacts on firm value. The coefficient of CASHD and CFOSALES are statistically significant at the one percent level, in all of the regression models. The results suggest that firms with higher cash flows have higher values. The interest variables NWC and CCC have negative coefficients that are significant at the one percent level, in all of the specifications. The empirical evidence suggests that a decrease in NWC is strongly associated with an increase in firm value. As a one-period lagged value of NWC is included in the model, this coefficient is also negative and significant at the one percent level, but the magnitude is lower than that of NWC. The R^2 is higher for the NWC models than for the NWC model with a one-period lag.

Table III documents the effects of NWC and CCC and its components on firm profitability. The dependent variable is ROIC. Table III shows evidence of a strong negative relationship between profitability and NWC, and CCC and its components, including DSO, DSI and DPO. On average, as a firm reduces its CCC by 100 days, its ROIC[2] increases by 1.05 percent. A reduction of 100 days in DSO, DSI and DPO is associated with an increase in ROIC by 1.35, 1.17 and 1.23 percent, respectively. A decrease of 1.00 percent in NWC is associated with an increase of 2.03 percent in ROIC.

The results in Tables II and III verify *H1*. The results are consistent with Shin and Soenen (1998), among others, in finding a negative association between firm performance and CCC. The results are also consistent with Aktas *et al.* (2015) in that this study finds a negative relationship between firm performance and NWC. More importantly, the evidence in this paper indicates that firm performance, as measured by either market or accounting value, is negatively associated with a firm's investment in NWC. The results imply a significant necessity of reducing the NWC level and the CCC in markets in Vietnam.

MTB	I	II	III	IV

Notes: This table reports the fixed time effects firm's profitability regression. The dependent variable, ROIC is the return on invested capital. CAPEX total capital expenditure scaled by total book assets, GROWTH the growth rate of sales, LEV leverage. SALES the total revenue, VOL the standard deviation of firm's daily stock returns, CCC cash conversion cycle, DSO days sales outstanding, DSI days sales inventory, DPO days payable outstanding, and NWC = (accounts receivable + inventory − accounts payable)/total book assets. The days are divided by 100. Numbers in parentheses represent the *p*-value

Table III. Cash conversion cycle, net working capital and profitability

5.2 The effects of ease to capital and business cycle

In order to examine the effects of access to capital, I divide the full sample into two groups, based on the firm's total government and foreign ownership. Due to government support, firms with high government ownership have better access to capital and lower borrowing costs (see, Sun and Tong, 2003; Le *et al.*, 2018). In addition, foreign investment in Vietnam's listed companies targets a long horizon. The availability of combined government and foreign ownership (GOVOWN) provides firms with access to capital.

Table IV shows evidence of a strong negative effect of NWC and CCC on firm value for firms whose GOVOWN is less than 50.00 percent. In the sub-sample of these firms, the coefficient of CCC is negative and significant at the one percent level, and the coefficient of NWC is negative and marginally significant at the one percent level. Nevertheless, these coefficients are insignificant in models that consist of firms whose GOVOWN is equal to or more than 50.00 percent. The absolute magnitudes of these coefficients are significantly higher for models of firms with a GOVOWN level that is less than 50.00 percent. The results verify *H2* and are consistent with Teach (2015). The results in this paper are also similar to findings in Malaysian markets (see Wasiuzzaman, 2015).

Table V includes regression results for ROIC as it is influenced by the business cycle. Stock markets in Vietnam declined from 2007 to 2012, and then recovered beginning in 2013. DUMMY is a dummy variable equal to 1 for the period 2007 to 2012 and zero for the period 2013 to 2016. I examine the effects of the business cycle by multiplying all of the explanatory variables on Table III by DUMMY; the regression results are summarized on Table V. All of the coefficients except for CAPEX × DUMMY and NWC × DUMMY are significant at the one percent level. The absolute magnitudes of product variables NWC × DUMMY, and CCC × DUMMY and its components are lower in Table V than are the variables themselves on Table III. For instance, the evidence in Table III shows that a decrease in CCC by 100 days is associated with an increase of 1.05 percent in ROIC.

MTB	GOVOWN ⩾ 50% I	II	GOVOWN < 50% I	II
CAPEX	0.17660 (0.216)	0.19170 (0.183)	0.15657 (0.256)	0.13976 (0.318)
INTEREST	0.52999 (0.554)	0.52331 (0.56)	−2.78973 (0.00)	−2.66468 (0.00)
CASHD	0.81089 (0.00)	0.82395 (0.00)	2.19465 (0.00)	2.28025 (0.00)

NWC × DUMMY					−0.74658 (0.524)
Firm- and year-fixed effects	Yes	Yes	Yes	Yes	Yes
R^2	0.1816	0.1805	0.1786	0.1764	0.1767
Number of observations	3,079	3,079	3,079	3,079	3,079

Notes: This table reports the fixed effects of business cycle. In Vietnam, the financial crisis period started with stock value drop in 2007 until 2012, and the recovery period began in 2013. The dependent variable is the return on invested capital. CAPEX total capital expenditure scaled by total book assets, GROWTH the growth rate of sales, LEV leverage. SALES the total revenue, VOL the standard deviation of firm's daily stock returns, CCC cash conversion cycle, DSO days sales outstanding, DSI days sales inventory, DPO days payable outstanding, and NWC the net working capital scaled by total assets at year end. The days are divided by 100. NWC = (accounts receivable + inventory − accounts payable)/total book assets. DUMMY equal to one for the period 2007–2012 during which stock markets declined by time, and equal zero for the period 2013–2016 where stock markets recovered. Numbers in parentheses represent the p-value

Table V.
The effects of business cycles

The results on Table V suggest that, during a downturn, a reduction in CCC by 100 days is associated with an increase in ROIC of only 0.89 percent. The evidence implies that a reduction in NWC, CCC, operating cycle and DPO have a lower effect on profitability during a crisis than during a recovery.

5.3 *The effects of WCM on stock-return volatility*

Following Coles *et al.* (2006) and Aktas *et al.* (2015), I use the annualized standard deviation of a firm's daily stock returns as a proxy for firm risk. In this section, I run a regression of stock-return volatility against NWC and a set of determinants. In all of the models, firm size, foreign ownership and NWC have strong and negative influences on stock-return volatility. The results imply that an additional investment in working capital reduces firm risk. Therefore, *H3* is verified. The result of a strong negative effect of foreign ownership on volatility is broadly consistent with previous studies (see, e.g. Li *et al.*, 2011). Sales growth rate and market-to-book ratio show strong positive impacts on stock-return volatility. The results show a lower fluctuation in stock prices during periods of stock-price declines than during periods when stock prices increase. The negative effects of investment in NWC on stock-return volatility found in this paper are consistent with Aktas *et al.* (2015) (Table VI) .

6. Conclusion

This paper uses a panel data set on markets in Vietnam, for the period 2007 to 2016, to document comprehensive evidence of the relationship between WCM and firm value, profitability and risk in an emerging market. The findings of this paper are important to firms' managers, investors and researchers. The paper shows that, in managing working capital, a firm's managers must trade-off between the objectives of profitability and risk control. Similarly, each investor has different return objectives and levels of risk tolerance. Hence, the levels of NWC that affect firms' performance should be considered in investors' decision making process. The results also imply that there exists an optimal level of NWC that balances firm profitability and risk. Figuring out an optimal NWC level is worthy of future research.

The direct relationship between the effects of NWC and the CCC on firm profitability and valuation suggests that when the levels of NWC or the CCC are reduced, firm performance, as measured by either market value or accounting value, also improves. The results of this paper also confirm the importance of efficient WCM, particularly in firms with less access to external financing, or during periods of economic recovery when firms expand their investments. This is also consistent with Teach (2015). Barely working: "The availability of cheap debt has reduced companies' incentive to improve working capital management."

Volatility	I	II
LOG(SIZE)	−0.73705 (0.00)	−0.72076 (0.00)

Firm- and year-fixed effects	Yes	Yes
R^2	0.6463	0.6454
Number of observations	3,078	3,078

Notes: This table reports the fixed effects regression results of stock volatility against net working capital and other factors. Stock volatility is stock return's standard deviation using daily return. SIZE the year-end total book assets. MTB the market to book ratio at year-end. AGE the months from firm's IPO to the date. NWC = (accounts receivable + inventory − accounts payable)/total book assets. OWN the percentage of shares owned by foreigners. GROWTH the growth rate of sales, LEV leverage. DUMMY equal to one for the period 2007-2012 during which stock markets declined by time, and equal zero for the period 2013–2016 where stock markets recovered. Numbers in parentheses represent the *p*-value

Table VI. Net working capital and firm risk

Notes

1. See Blenman and Le (2014).
2. To test for robustness, I also ran a fixed-effects regression of the net profit margin (net income/ sales) against NWC, and CCC and its components. The results also show a strong negative relationship between the net profit margin and NWC, CCC and DSO and DPO. The coefficient of DSI is negative but insignificant.

Abstract

Purpose – The purpose of this study is to introduce working capital efficiency multiplier (WCEM) as a direct profitability measure of working capital management. The existing accounting measures in the literature establish an indirect approach to study the relationship between working capital efficiency and profitability of the firms.

Design/methodology/approach – Using the help of a set of companies from CMIE Prowess database, the study introduces WCEM as a direct profitability measure of working capital efficiency.

Findings – In this study, a new direct measure of working capital efficiency is introduced which is multiplicative in nature. WCEM is a product of three components, namely, WACC, ratio of the sum of trade receivables and inventories to trade payables and ratio of net working capital (NWC) to net sales.

Practical implications – The importance of direct measure like WCEM could be enormous in performance evaluation of a firm. It can be used as an indicator for choosing a suitable investment opportunity by an investor. This is due to the fact that the firm that is highly efficient in managing working capital is less exposed to liquidity risk. At the same time, the firm is less dependent on external financing. Therefore, such firms eventually create more value for their shareholders. Another indication that WCEM provides is to gauge the bargaining power of the firm and its competitive position in the market. Lower WCEM indicates higher bargaining power of a firm across the value chain, and its superior position relative to its competitors.

Originality/value – Most of the studies on WCM are of the empirical type and there is a complete dearth on theoretical framework. Researchers hereafter can consider WCEM as one of the financial performance variables in place of the existing measures such as return on asset (ROA), return on invested capital (ROIC), return on equity (ROE), gross operating income (GOI) and net operating income (NOI) and thereby can contribute new empirical insights through their research outcomes.

Keywords WCM, Direct profitability measure, WCEM, Working capital efficiency

1. Introduction

In today's ever-changing business environment, survival of the business is the driving force for a firm to excel among its peers. Survival in the modern world (continuing to be in business) is possible, only, when apart from other things, a firm has sufficient amount of financial resources to meet its long-term (fixed capital) and short-term commitments

DOI 10.1108/JIBR-02-2018-0056

(working capital). The management of working capital is equally important as the management of long-term financial investment because efficient utilization of fixed assets is possible only when the company has adequate amount of working capital and it affects not only short-term financial performance, i.e. profitability (Raheman and Nasr, 2007; Samiloglu and Demirgunes, 2008), but also long-term financial performance, i.e. maximization of firm value (Samiloglu and Demirgunes, 2008). Working capital efficiency is a measure that indicates how a firm balances the amount of capital blocked in receivables and inventories with its payables on purchase of inventories. To be more specific, this measure differentiates the firms of similar nature (e.g. similar size, nature of business etc.) based on the portion of the funds mobilized to meet their day-to-day operating requirements (Dong and Su, 2010). Besides, working capital efficiency of a firm denotes the firm's creditworthiness and creates an investor's opinion on the firm's financial health. The firm with high working capital efficiency minimizes the need for borrowed capital in the short-run and thus helps the business to plan for long-term borrowing while expanding or investing in new projects.

Maintaining a desired level of working capital efficiency drives firm managers to take timely decisions relating to investment in current assets and short-term financing. Such decisions are important features of working capital management (WCM) (Nimalathasan, 2010). WCM has become one of the non-trivial issues in organizations, where many finance managers find it difficult to distinguish the important drivers of working capital and to decide on the optimal level of working capital (Smith, 1987; Lamberson, 1995). Most of the studies have focused on working capital practices of firms belonging to developed countries and very few studies reflect the same of firms operating in emerging economies, such as India (Saravanan *et al.*, 2017).

Cash conversion cycle (CCC) is the most popular and widely used measure of working capital efficiency. It is the sum of days' inventories and days' receivables minus days' payables. The longer the CCC, the larger is the investment in working capital (Deloof, 2003; Abuzayed, 2012). According to the WCM Report 2014, released by consulting firm Ernst & Young, the top 500 Indian companies had an average CCC of 67 days compared with 42 days for US firms, 41 days for European companies and 39 days for the firms in the rest of Asia. The report concludes that the top Indian firms might have increased their cash flows by Rs. 5.3tn in the financial year 2014 if they had effectively managed their working capital cycle. Therefore, it is imperative to find a suitable and innovative performance (outcome) measure which clearly and directly reports the impact of working capital efficiency of the firms.

As of now, there are a number of studies that have reported the impact of CCC on the profitability of companies (Wang, 2002; Deloof, 2003; Samiloglu and Demirgunes, 2008; Falope and Ajilore, 2009; Mathuva, 2009; Dong and Su, 2010; Banos-Caballero *et al.*, 2012; Saravanan *et al.*, 2017). These studies, in general, have used return on asset (ROA), return on invested capital (ROIC), return on equity (ROE), gross operating income (GOI) and net operating income (NOI) as a proxy for profitability of firms. It is quite logical to state that the profit earned by a firm is generated from its investment in both non-current assets and current asset or working capital. Therefore, if one needs to capture the relationship between working capital efficiency and profitability of a firm accurately, he/she needs to consider only that part of profit which is generated by efficient WCM. However, the above-stated profitability measures such as ROA, ROIC and ROE do not segregate the return earned by firms on their non-current assets and working capital. The other two measures (GOI and NOI) also fail to distinguish between the profit earned on net working capital (NWC) and that of using the non-current assets, and hence, there is a need to develop a direct outcome measure to exclusively assess the impact of a firm's investment in working capital.

We, in this study, introduce a direct performance measure of working capital efficiency, namely, working capital efficiency multiplier (WCEM). Contribution of this study to the existing literature is of many folds. Firstly, to the best of our knowledge, this is the first study which proposes WCEM as an effective direct measure of performance while expressing the logical relationship between firms' working capital efficiency and their working capital cost (WCC). Secondly, although the evidences in favor of this direct measure have been provided on the basis of Indian firms, it can be widely applied to firms from any other country. Lastly, the WCEM is easy to compute and hence not much expensive in decision making.

The remainder of the paper is structured in the following manner. Section 2 deals with a review of the literature on the management of working capital. Section 3 presents the rationale for the development of a direct performance measure to investigate the impact of working capital efficiency on the financial performance of firms. WCEM as a direct outcome measure of working capital efficiency is presented in Section 4. Finally, Section 5 concludes and provides the scope for future research.

2. Review of literature

A significant portion of earlier research on WCM has been extensively investigated at empirical levels (Singh and Kumar, 2014; Enqvist *et al.*, 2014; Aktas *et al.*, 2015). Corporate finance literature traditionally focuses on long-term financial decisions and their impact on the profitability of firms. However in recent years, WCM has gained importance, as managers and academicians have recognized the relevance of efficient management of working capital in the survival of a firm, especially after the global financial turmoil (Uremandu *et al.*, 2012; Ramiah *et al.*, 2014). Improper management of working capital is a major reason for the failure of small- and medium-sized firms compared to large firms in developed economies like USA and UK (Dunn and Cheatham, 1993; Peel and Wilson, 1996). Management of working capital involves the manager's time, attention and skills in handling short-term investments and the objective of WCM is to increase the liquidity and profitability of the firms and thereby increase their shareholders' value (Chang, Dandapani and Prakash, 1995; Nilsson, 2010; Aktas *et al.*, 2015).

Operational working capital is mainly used to measure the cycle times or turnover times of various components of WCM such as inventories, accounts receivables, accounts payables, etc. and is designed to assess managerial decision making (Filbeck and Krueger, 2005). The operational working capital measures can be used to quantify the working capital efficiency of firms and their managers (Hofmann and Kotzab, 2010). The CCC, as discussed earlier, is the basic measure of operational working capital (Richards and Laughlin, 1980). There are several variations of CCC in the academic literature. Richards and Laughlin (1980) calculate CCC as presented below:

$$\begin{aligned} CCC = {} & \frac{Inventories}{COGS} * 360 + \frac{Notes\ and\ accounts\ receivables}{Net\ sales} * 360 \\ & - \frac{Accounts\ payables - Salaries,\ benefits\ and\ payroll\ tax}{COGS + Selling,\ general\ and\ Administrative\ expense} * 360 \end{aligned} \tag{1}$$

Theodore Farris and Hutchison (2002) as well as Ding *et al.* (2013) use a simpler equation for CCC as presented below:

$$CCC = \frac{Inventories}{COGS} * 365 + \frac{Accounts\ receivables}{Net\ sales} * 365 - \frac{Accounts\ payables}{COGS} * 365 \quad (2)$$

The simplest variation of CCC is net trade cycle (NTC) which was developed by Shin and Soenen (1998). NTC uses net sales as the denominator for all the three components of working capital.

$$NTC = \frac{Inventories + Accounts\ receivables - Accounts\ payables}{Net\ Sales} * 365 \quad (3)$$

CCC deals with three major components of working capital, namely, inventory, accounts receivables and accounts payables, in such a way that it reveals composite performance of a firm in terms of its working capital efficiency. The weighted cash conversion cycle (WCCC) provides more detailed information than the original CCC (Gentry, 1990). WCCC connects the monetary values of operational working capital components to their cycle times. WCCC can be concluded as weighted operating cycle less weighted days in accounts payables. WCCC is extended into adjusted cash conversion cycle (ACCC) (Viskari *et al.*, 2012). The calculation logic of ACCC is based on WCCC, but it could be used on customer or product levels. The modifications present the efficiency of WCM in days which is similar to the original CCC.

The existing literature consists of a number of studies which employ CCC as the measure of working capital efficiency and conclude that a firm can improve its efficiency in WCM by reducing its CCC (Emery, 1987; Blinder and Maccini, 1991; Deloof and Jegers, 1996; Raheman and Nasr, 2007; Nobanee, Abdullatif and AlHajjar, 2011). Therefore, a firm can acquire competitive advantage through proper WCM.

Profitability is used as a measurement for financial performance because it evaluates the efficiency with which plant, equipment and net current assets are transformed into profits (Kamal and MohdZulkifli, 2004). There are a number of past studies that describe the relationship between working capital efficiency and profitability of firms using ROA as a proxy for profitability (Jose *et al.*, 1996; Shin and Soenen, 1998; Wang, 2002; Samiloglu and Demirgunes, 2008; Falope and Ajilore, 2009; Mohamad and Saad, 2010; Charitou *et al.*, 2010; Vahid *et al.*, 2012a, 2012b; Saravanan *et al.*, 2017). Instead of ROA, few studies prefer ROIC as a measure of profitability which reports the profits earned by the firms on their long term capital invested or long-term capital employed (Mohamad and Saad, 2010; Nobanee *et al.*, 2011). ROE which reports the profits earned by a firm for its equity shareholders is another widely used measure of profitability (Jose *et al.*, 1996; Wang, 2002). Moreover, researchers often use GOI which reveals the gross operating profits earned by a firm on its total assets (Deloof, 2003; Gill *et al.*, 2010; Dong and Su, 2010; Banos-Caballero *et al.*, 2012; Abuzayed, 2012). In addition, NOI which indicates the net operating profit earned by a firm on its total assets (Deloof, 2003 for the difference between GOI and NOI) has also been used for the same purpose (Shin and Soenen, 1998; Banos-Caballero *et al.*, 2012).

Academic research work carried on the relationship between CCC and profitability of firms have reported a mixed evidence where few of them have reported a positive relationship (Shin and Soenon,1998; Padachi, 2006; Mathuva, 2009; Dong and Su, 2010; Banos-Caballero *et al.*, 2010; Raheman *et al.*, 2010) and many of them have reported a negative relationship (Kim *et al.*, 1998; Wang, 2002; Deloof, 2003; Zariyawati *et al.*, 2009; Ching *et al.*, 2011; Akinlo, 2012; Abiodun and Samuel, 2014; Saravanan *et al.*, 2017) between the two variables.

Soenen (1993) investigates the relationship between NTC and return on investment in the US firms and find a negative relationship between the two variables. Jose *et al.* (1996) examine the relationship between CCC and profitability by considering a large number of the American firms and report a significant negative relationship between CCC and profitability. They also observe that more aggressive WCM is associated with higher profitability. Shin and Soenen (1998) report a strong negative relationship between NTC and the firm's profitability and they suggest that one possible way for managers to create shareholder value is to reduce their firms' NTC.

Wang (2002) examines the relationship between CCC and profitability (measured by ROA and ROE) of 1555 Japanese firms and 379 Taiwanese firms and concludes that reducing CCC enhanced operating performance in spite of differences in the structural characteristics of both these countries. Deloof (2003) used a sample of 1,009 large Belgium firms for the period of 1992 to1996 and concludes that firms can improve their profitability by reducing the number of days of accounts receivable and inventories to a reasonable minimum. This negative relationship between CCC and profitability is consistent with the view that more profitable firms are efficient in managing their working capital.

Lazaridis and Tryfonidis (2006) study the relationship between firms' profitability (through gross operating profit) and the working capital efficiency (through CCC) for the listed firms in Athens Stock Exchange and report that if CCC is kept at the optimal level it may positively affect the shareholders' wealth. Garcia-Teruel and Martinez-Solano (2007) analyze small and medium size European companies and observe that shortening the CCC improves a firm's profitability.

Falope and Ajilore (2009) analyze a sample of 50 Nigerian quoted non-financial firms using panel data regression and document a significant negative relationship between net operating profitability and CCC, the average collection period, inventory storage days and average payment period. Further, they show no significant variation in the effects of WCM between large and small firms. A significant and positive relationship between the CCC and firms' profitability has been established by Gill *et al.* (2010) using a sample of 88 firms listed on New York stock exchange. This means that longer the CCC, higher is the profitability of the firm.

From the above discussion, we can conclude that a firm can generate an additional amount of cash by reducing its CCC which in turn can be used for investment in operating assets and thereby increasing the profitability of the firm. Hence the studies reported in the literature on WCM postulate an indirect relationship between CCC and profitability of the firms as shown in Figure 1.

However, the literature is very silent about any sort of direct and explicit relationship between working capital efficiency and financial performance of firms which leads us to the following research question:

RQ. Is it possible for a firm *to directly measure the impact of* its working capital efficiently on its financial performance?

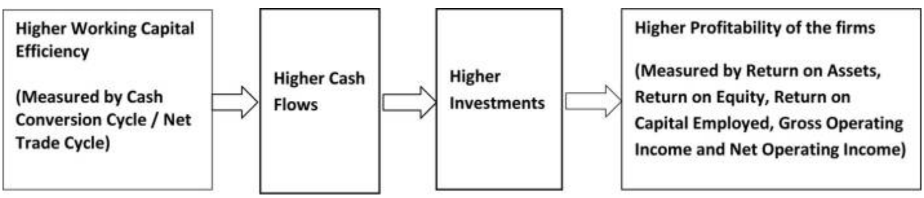

Figure 1.
Indirect relationship between working capital efficiency and profitability of the firms assumed by existing literature

3. Rationale for the development of a direct performance measure in assessing the impact of working Capital efficiency

Capital structure theories (Modigliani and Miller, 1958; Modigliani and Miller, 1963; Miller, 1977; Jensen and Meckling, 1976; Titman and Wessels, 1988; Myers and Majluf, 1984; Harris and Raviv, 1991) state that firms can optimally design their capital structure in order to increase their value. In other words, a firm can change its value by changing its financing mix.

It is logically apparent that if firms can have differences in their capital structure then they can also have differences in their asset structure i.e. proportion of non-current assets and NWC. If this is true, then the differences in the asset structure of firms in general, and the differences in the working capital efficiency of firms in particular, should lead to differences in financial performance of the firms. However, the existing profitability measures such as ROA, ROIC, ROE, GOI and NOI do not explicitly reveal the differences in the asset structure of firms in general and the differences in their efficiency in using investments in particular (see Table I). Hence, the question that comes to our mind is that whether the impact of working capital efficiency on financial performance of firms can be measured in a direct manner by developing a new financial outcome measure?

Table I. Rationale for development of new financial performance measure, WCEM

Profitability measure	Does the measure explicitly report the impact of working capital efficiency of firms	Reason for non-suitability in measuring the impact of working capital efficiency of firms
Return on Asset (ROA) Jose *et al.* (1996), Shin and Soenen (1998), Wang (2002), Samiloglu and Demirgunes (2008), Falope and Ajilore (2009), Mohamad and Saad (2010), Charitou *et al.* (2010), Vahid *et al.* (2012), Saravanan *et al.* (2017)	No	Reports the return made on employment of total assets and does not segregate the return on NWC and return on non-current assets from the composite measure of ROA
ROIC Mohamad and Saad (2010), Nobanee *et al.* (2011)	No	Reports the return on invested capital but does not decompose ROIC into return on NWC and return on non-current assets
Return on equity (ROE) Jose *et al.* (1996), Wang (2002)	No	Reports return on shareholders' funds but fails to report return on NWC and return on non-current assets
GOI Deloof (2003), Gill *et al.* (2010), Dong and Su (2010), Banos-Caballero *et al.* (2012), Abuzayed (2012)	No	Reports gross operating profit as a percent of total assets but fails to disclose the return on NWC and return on non-current assets
Net operating income (NOI) Shin and Soenen (1998), Deloof (2003), Banos-Caballero *et al.* (2012)	No	Reports net operating profit as a percent of total assets but fails to disclose the return on NWC and return on non-current assets

Notes: This table lists the existing literature that have used different profitability measures such as return on assets (ROA), return on invested capital (ROIC), return on equity (ROE), gross operating income (GOI) and net operating income (NOI); further it explains the reasons why such studies are not suitable in measuring the impact of working capital efficiency of firms

To verify our point presented in the preceding paragraph, we have collected the sample data from Prowess database, created by the Centre for Monitoring Indian Economy (CMIE). This database contains detailed information on the financial indicators of Indian firms, compiled from various sources such as profit and loss accounts, balance sheets, cash flow statements and annual reports. This is a reliable source of information which many researchers have used extensively in other empirical works in financial economics (Bertrand *et al.*, 2002; Sarkar and Sarkar, 2000; Saravanan *et al.*, 2016).

In this study, we have used NTC as the proxy for measuring the working capital efficiency due to the following reasons (Shin and Soenen,1998; Ganesan,2007 and Raheman *et al.*,2010). First, WCCC which is a modified version of CCC and developed by Gentry *et al.* (1990) scales the timing by the amount of funds tied up in each step of the cash cycle but the break-up of the components of inventories (raw materials, work-in progress and finished goods) is not readily available in the annual reports and hence we cannot calculate WCCC. WCCC is extended into ACCC (Viskari *et al.*, 2012). The calculation logic of ACCC is based on WCCC but it could be used on customer or product levels. Second, CCC is an additive measure and the denominators of days' inventories, days' accounts receivables and days' accounts payables are all different, making it difficult to compute. Whereas, NTC is basically CCC wherein all the three components (days' inventories, days' accounts receivables and days' accounts payables) are expressed as a percentage of sales. This measure is easy to compute and can be expressed as a function of the projected sales growth. Hence, NTC is used as a measure of working capital efficiency in this study.

We have computed the NTC, ROA, ROIC [or ROCE], ROE, GOI and NOI (please see Note at the end for formulae) for a pair of firms operating in the same industry as the working capital practices and the profitability of firms may get affected by the industry characteristics (Weinraub and Visscher, 1998). The results are presented in Table II.

From Table II, it is evident that two companies, namely JSW Energy Ltd. and RattanIndia Power Ltd., operating in the conventional electricity industry have reported the same ROA of 11 per cent. However, JSW Energy Ltd. has a NTC of 22 days while RattanIndia Power Ltd. has a NTC of 123 days. This indicates that the two firms operating in the same industry with same ROA figures differ with reference to their efficiency in managing working capital. Similarly, we spot differences in working capital efficiency (measured by NTC) between a pair of firms across industries in spite of reporting the same ROCE or ROE or GOI or NOI. For instance, Ambalal Sarabhai Enterprises Ltd. with a NTC of 64 days is relatively efficient in WCM compared to its competitor, Andrew Yule and Co. Ltd. (with a NTC of 90 days) even though both of these firms have generated the same GOI of 9 per cent.

From the above discussion, we can recognize that the existing profitability measures do not explicitly reflect the impact of working capital efficiency of firms. For instance, literature has used Return on Asset (ROA) (Shin and Soenen, 1998; Padachi, 2006; Mohamad and Saad, 2010), Return on Invested Capital (ROIC) (Vishnani and Shah, 2007; Mohamad and Saad, 2010) Return on Equity (ROE) (Afza and Nazir, 2008; Akoto *et al.*, 2013), gross operating income (GOI) (Deloof, 2003;Ganesan, 2007; Alipour, 2010) and net operating income (NOI) (Raheman and Nasr, 2007; Zairyawari *et al.*, 2009) as a proxy for profitability of firms (outcome measure of WCE of firms). Hence, there arises a need to replace the traditional measures of profitability with a new measure which can describe an explicit and direct relationship between working capital efficiency and financial performance of the firms as indicated in Figure 2.

From Figure 2, it can be stated that firms with higher working capital efficiency (lower NTC) may generate higher financial performance. Financial performance of firms could be

Table II. Comparison of traditional and naïve financial performance measures with NTC of sample firms

Company name	Industry group	Traditional performance measures	Performance (in %)	NTC (in days)	(a) RONWC using the contents of balance sheet and income statement: NWC (in Rs. million	CE (in Rs. million	NWC/CE	ROCE	RONWC = ROCE × (NWC/CE)

Notes: This table compares traditional and naïve financial performance measures with net trade cycle (NTC) of sample firms. The four traditional measures which gauge the effect of working capital efficiency of firms are: (a) return on net working capital (RONWC) using the content of balance sheet and income statement; RONWC = ROCE × (NWC/CE) (b) return on net working capital (RONWC) using the content of balance sheet, income statement and annual report; RONWC = (working capital profit/NWC) × 100 (c) working capital expenses using the content of annual report; and (d) working capital cost (WCC) using contents from balance sheet and CMIE Prowess database; WCC = WACC × NWC; Log WCC is logarithm of WCC

(*continued*)

proxied by the cost of capital blocked in NWC of a firm which can be measured through WCEM as proposed by the authors in this study. We argue that firms with higher working capital efficiency have lower cost of capital for their investments in working capital. Lower the WCEM, lower is the cost of capital blocked in NWC and therefore higher is the financial performance of a firm (refer Table III).

4. Working capital efficiency multiplier as a direct outcome measure of working capital efficiency

In this section, we first present the naive approaches that may be used in quantifying the impact of the efficiency of firms in managing their investments in working capital. The naïve approaches have serious limitations such as being additive in nature besides not capturing behavioral impacts in an objective manner. We end our discussion with the formulation of WCEM, which we argue to be the right outcome measure of working capital efficiency of firms.

4.1 Naive approaches

To gauge the effect of working capital efficiency of firms, one may consider the following four alternatives:

(1) Return on net working capital (RONWC) using the content of balance sheet and income statement;

(2) Return on net working capital (RONWC) using the content of balance sheet, income statement and annual report;

(3) Working capital expenses using the content of annual report; and

(4) WCC using the content of balance sheet and annual report.

4.1.1 Return on net working capital using the contents of balance sheet and income statement. As discussed in the previous section, companies differ in their asset structures. In the extant literature, return on capital employed (ROCE) is used extensively as a proxy for profitability of firms. ROCE reflects the return on the total capital employed by firms, which can be decomposed into return on net working capital (RONWC) and return on non-current assets (RONCA). As a naive approach, we may compute the RONWC by multiplying the ROCE by the proportion of NWC in the total capital employed by a firm.

For instance, the ROCE of JK Lakshmi Cement Ltd. (Table II) is 6 per cent, NWC is Rs. 1,005m and capital employed is Rs. 2,300m, and its NWC/capital employed is 0.44 and then its RONWC = 6 × (0.44) = 2.64 per cent.

This is a very simple approach as we can easily get the ROCE and proportion of NWC in total capital used from the balance sheets of firms. However, this approach has a major drawback as the actual proportion of ROCE from the employment of NWC may differ substantially from the theoretical proportion (proportion of NWC in the total capital

Figure 2.
Proposed direct relationship between working capital efficiency and financial performance of the firms

Notes: This table compares traditional and proposed financial performance measures, i.e. working capital efficiency multiplier (WCEM), with net trade cycle (NTC) of sample firms. It also identifies trade receivables, inventories, trade payables, net trade cycle and weighted average cost of capital (WACC) as a determinant of WCEM. WACC has been calculated from cost of debt (COD) and cost of equity (COE) which are calculated from annual reports of the companies and using CAPM respectively. WACC = after-tax COD × proportion of Debt + COE × proportion of Equity. Pretax COD = (interest expenses/ (short-term borrowing + long-term borrowing) × 100. Posttax COD − pretax COD × (1 − tax rate). COE = risk-free rate + beta (market risk premium). Risk-free rate is taken as 6.9% and market risk premium is 6.06%. Beta values are taken from CMIE Prowess database for the firms. WCEM has been calculated as WACC × (trade receivables + inventories)/trade payables × (NTC/365)

$$Return\ on\ assets\ (ROA) = \frac{EBIT(1-t)}{Total\ assets}$$

$$Return\ on\ Capital\ Employed(ROCE) = \frac{EBIT(1-t)}{Invested\ Capital}$$

$$Return\ on\ Equity(ROE) = \frac{Profit\ after\ tax}{Owners'\ Equity}$$

$$Gross\ Operating\ Income\ (GOI) = \frac{Sales - Cost\ of\ sales + Depreciation\ \&\ Amortization}{Total\ Assets}$$

$$Net\ Operating\ Income\ (NOI) = \frac{Sales - Cost\ of\ Sales}{Total\ Assets}$$

employed using the balance sheet). This is due to the differences that may exist in the efficiency of managers in managing non-current and net-current assets of their firms, and it is not possible for us to trace out the same. Hence, this approach may not be the right one in our attempt to truly reflect the working capital efficiency of firms.

4.1.2 Return on net working capital using the contents of balance sheet, income statement and annual report. We may compute RONWC by dividing the amount of working capital profit of a firm by its investment in NWC. We may compute working capital profit as stated below:

$$\begin{aligned} \textit{Working capital profit} = {} & \textit{Operating revenue from usage of working capital} \\ & - \textit{Working capital expenses} \end{aligned} \quad (4)$$

where:

$$\begin{aligned} \textit{Operating revenue from working capital} = {} & \textit{Total Operating Revenue} \\ & * \left(\frac{NWC}{\textit{Total Capital Employed}} \right) \end{aligned} \quad (5)$$

$$\begin{aligned} \textit{Working Capital Expenses} = {} & (\textit{Raw material consumed} \\ & \pm \textit{Changes in work in progress and finsihed goods inventory} \\ & + \textit{consumption of stores and spare parts} \\ & + \textit{Damaged material, Obsolescence,} \\ & \quad \textit{write down of inventories} + \textit{Bad Debts}) \end{aligned} \quad (6)$$

$$\textit{Net Working Capital} = \textit{Inventories} + \textit{Trade Receivables} - \textit{Trade Payables} \quad (7)$$

We can collect the data for the above-stated variables from the annual reports of firms as well from CMIE Prowess database. For instance, total operating revenue of JK Lakshmi Cement Ltd. is Rs. 45,930m, its NWC/CE is 0.44, working capital expenses is Rs. 19,539m and NWC is Rs. 1,005m then its working capital profit is (45,930 $\times$ 0.44) $-$ 19,539 = Rs. 670m. The RONWC of the firm is [(670/1,005) $\times$ 100] = 66.67 per cent (Table II).

This approach considers the working capital expenses that are explicit and are related to inventories and trade receivables. However, we are finding out the revenue from working capital using the proportion of working capital in total capital employed which has the same drawback as that of the previous approach. Therefore, this is also an inappropriate approach to report the effect of the working capital efficiency of managers.

4.1.3 Working capital expenses using the contents of annual report. The limitation of the previously discussed naive approaches is that they are based on the theoretical proportion of NWC in the total capital employed by firms. Further, the second approach focuses on computing the profit from the employment of working capital which requires us to calculate the revenue and expenses related to a firm's investment in working capital. Instead of considering the revenue and profit as the outcome of the working capital efficiency of firms, we may consider the working capital expenses as the proxy for the financial performance of firms in our attempt to measure the impact of working capital efficiency of managers. The advantage of this approach is that one may easily get the data on the working capital expenses of firms from their annual reports or from the databases such as CMIE. Working capital expenses is computed as stated in equation (6) earlier:

$$\begin{aligned} \textit{Working Capital Expenses} = (&\textit{Raw material consumed} \\ &\pm \textit{Changes in work in progress and finsihed goods inventory} \\ &+ \textit{consumption of stores and spare parts} \\ &+ \textit{Damaged material}, \textit{Obsolescence}, \\ &\textit{write down of inventories} + \textit{Bad Debts}) \end{aligned}$$

For instance, the working capital expense of JK Lakshmi Cement Ltd. is Rs. 19,539m where the raw material consumed is Rs. 15,813m, changes in work in progress and finished goods inventory is Rs. 169.9m, consumption of stores and spare parts is Rs. 3,896m, damaged material, obsolescence, written-down inventories and bad debts is zero.

The drawback of this approach is that the working capital expenses is computed by collecting the expenses related to two of the working capital components, namely, inventories and trade receivables that are reported by firms in their annual reports and the cost of delaying payment to suppliers is implicit and not reported by firms in their annual reports. Hence, this approach may not be the right one to reveal the impact of working capital efficiency of managers.

4.1.4 Working capital cost using the contents of balance sheet and annual report. NWC is the excess of the sum of inventories and trade receivables over the trade payables of a firm. The amount of investment made by a firm in its inventories and receivables can be considered as wastage of capital (blockage of capital) by the managers of firms as these two current assets do not earn any return on their investments. However, a firm may reduce the ill-effect of its investments in inventories and trade receivables by increasing its dues to suppliers of materials and other services (trade payables). For instance, JK Lakshmi Cement Ltd. has the following figures: inventories at Rs. 805m, trade receivables at Rs. 600m and trade payables are at Rs. 400m. The amount of mobilized capital wasted by the firm is Rs. 1,005m = Rs. 805m + Rs. 600m − Rs. 400m.

This Rs. 1,005m investment made by a firm is sourced from short-term borrowings, long-term borrowings and equity capital of the firm. Every one rupee mobilized in the form of short-term borrowing, long-term borrowing and equity capital has a weighted cost. We may compute the weighted average cost of capital (WACC) of the firm using its annual reports (for computing cost of debt) and databases (for computing cost of equity using its equity beta from CMIE Prowess database, risk-free rate of 6.9 per cent and risk premium at 6.06 per cent) . For instance, the weighted average cost of capital for this firm is 7.85 per cent (Table II).

It is rational to state that the cost of the firm's investment in working capital is the product of its investment in working capital and its WACC. We may term this as working capital cost (WCC). For instance, the WCC for J K Lakshmi Cement Ltd. is Rs. 78.89m = Rs. 1,005m × 0.0785.

We can observe from Table II that two firms operating in the same industry with differences in their working capital efficiency (measured through NTC) have reported different WCC. For instance, Parnax Lab Ltd. is relatively efficient in its WCM (NTC of 57 days) compared to Parenteral Drugs (India) Ltd. (NTC of 128 days) operating in the same industry. Both the firms have reported same ROE of 8 per cent, while the absolute and log values of WCC of Parnax Lab Ltd. is quite lower (absolute WCC at Rs. 1,467m and log of WCC at 3.17) compared to that of Parenteral Drugs (India) Ltd. (with an absolute WCC of Rs. 12,733m and log of WCC at 4.10). Similarly, we can find differences among firms across industries in the working capital efficiency which is getting reflected in the absolute and log value of WCC of the respective firms.

Therefore a firm can reduce its working capital cost by reducing its NWC by improving its efficiency in managing NWC. However this measure gives us an absolute figure for WCC [say, for instance, Rs. 12,733m for Parenteral Drugs (India) Ltd.] and if we assume that the WCC for the same firm as Rs. 10,733m in the previous year, then we may conclude that the firm's WCC has increased in the current year compared to that of the previous year, that is all. We are unable to compare firms on inter-firm and intra-firm basis using WCC as it is an absolute figure. The problem still remains even after conversion of the absolute figure of WCC into logarithm form. Hence there is a need to look for an appropriate outcome measure for assessing the impact of working capital efficiency of firms.

4.2 Working capital efficiency multiplier – the right financial performance metric to measure the impact of working capital efficiency of firms

In this study we introduce a new and direct measure of working capital efficiency which is multiplicative in nature. It is similar like the DuPont multiplier. We term it as WCEM and express it as:

$$\begin{aligned} &\textit{Working Capital Efficiency Mutiplier}\ (\textit{WCEM}) \\ &= \textit{WACC} * \frac{\textit{Trade Receivables} + \textit{Inventories}}{\textit{Trade Payables}} * \frac{\textit{NTC}}{365} \end{aligned} \tag{8}$$

where:

WACC refers to weighted average cost of capital

NTC is:

$$NTC = \frac{\textit{Inventories} + \textit{Accounts receivables} - \textit{Accounts payables}}{\textit{Net Sales}} * 365$$

Substituting the value of NTC in WCEM, we get:

$$\begin{aligned} \textit{WCEM} = \textit{WACC} * &\frac{\textit{Inventories} + \textit{Trade Receivables}}{\textit{Trade Payables}} \\ &* \frac{\textit{Trade Receivables} + \textit{Inventories} - \textit{Trade Payables}}{\textit{Net Sales}} \end{aligned} \tag{9}$$

WCEM reflects the portion of WACC that is expensed by a firm for its investment in NWC. As formulated above, lower the value of WCEM of a firm, higher is its working capital efficiency. From Table III, we can observe that two firms, namely, JK Lakshmi

Cement Ltd. and KCP Ltd. have reported same ROCE at 6 per cent for their latest financial year (2017). However, we can observe the differences in their NWC investments and working capital efficiency measured through NTC. We argue that traditional performance measures are aggregates in nature which fail to segregate the profits earned by a firm from the employment of NWC, and these measures do not reflect the differences in their working capital efficiency of firms. The naïve approaches as described in the section do a comparatively better job to that of the traditional measures used by the extant literature. However the naïve approaches have serious limitations and hence may not use them in our attempt to assess the working capital efficiency of firms. WCEM for JK Lakshmi Cement Ltd. (with an NTC of 13 days) is computed to be 0.36 per cent, while that of KCP Ltd. is 11.87 per cent (with an NTC of 84 days). Similarly, we can find the WCEM for all other sample firms and see the reflection of differences in working capital efficiency of firms (see Table III).

Further, WCEM is simple to compute, and it is easy to explain the outcome of the working capital efficiency of firms. Hence, WCEM is a simple and flawless financial performance measure which reveals the true impact of the working capital efficiency of firms. Academics and practitioners may consider using WCEM in measuring the relationship between working capital efficiency and financial performance of firms in their empirical work.

4.2.1 Determinants of working Capital efficiency multiplier. From the above-stated formulation, we can arrive at the determinants of WCEM of a firm. They are: (Figure 3).

- trade receivables;
- inventories;
- trade payables; and
- WACC
- ratio of NWC to net sales

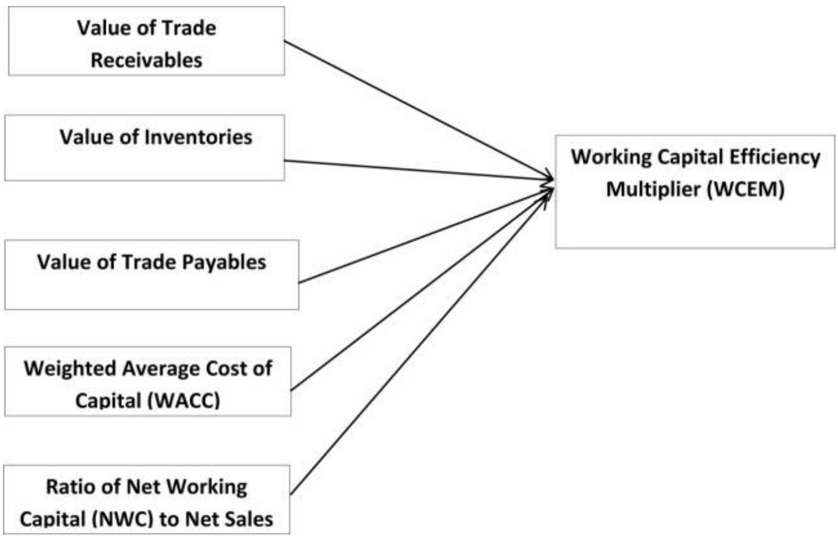

Figure 3. Determinants of WCEM

Keeping other variables constant, a decrease (increase) in trade receivables, inventories, WACC and ratio of NWC to net sales, decrease (increase) the WCEM for firms, while an increase (decrease) in trade payables, decrease (increase) the WCEM for firms.

5. Conclusion and scope for future research

Academic literature that explores the relationship between working capital efficiency and profitability of firms has so far considered CCC or NTC as a proxy for working capital efficiency, and accounting measures such as ROA, ROE, ROCE, GOI and NOI as the measure of profitability of the firms. The limitation of these studies is that the profitability (outcome) measure considered by them does not directly measure the impact of the working capital efficiency of firms as the measures (ROA, ROE, ROCE, GOI and NOI) report the aggregate return earned by firms from the employment of both the non-current assets and net current assets. Our study introduces WCEM as a direct financial performance (outcome) measure of working capital efficiency which can be widely used by academicians and practitioners.

If firms can change their profits by employing different proportion of financing mix, then they can also vary their profits by employing different proportion of asset mix and improve their financial performance by improving their efficiency in managing non-current and net current assets. In other words, asset structure and asset management efficiency determines the financial outcomes of a firm.

The importance of WCEM could be enormous in performance evaluation of a firm. It can be used as an indicator for choosing a suitable investment opportunity by an investor. This is due to the fact that the firm that is highly efficient in managing working capital is less exposed to liquidity risk. At the same time, the firm is less dependent on external financing. Therefore, such firm eventually creates more value for their shareholders. Another indication that WCEM provides is to gauge the bargaining power of the firm and its competitive position in the market. Lower WCEM indicates higher bargaining power of a firm across the value chain and its superior position relative to its competitors.

The researchers hereafter can consider WCEM as the financial performance variable in place of the existing measures and thereby contribute new theoretical insights through their research outcomes. Researchers can also test empirically the relationship between CCC/NTC and log of WCEM in both developed and developing markets. The relationship between the liquidity and WCEM and between working capital utilization and WCEM can also be studied by the researchers in the future.

Abstract

Purpose – The purpose of this paper is to examine the relationship between working capital management (WCM) and firm performance in the context of the Chinese economy. Specifically, it investigates the effects of ownership structures as an internal factor and of institutional environments (IE) as an external factor shaping this relationship.

Design/methodology/approach – The study applies two-way fixed effect regression models to a sample of Chinese listed manufacturing firms for the period of 2010 to 2017. WCM is measured by cash conversion cycles (CCC); profitability is measured by core profit ratios; ownership structures are classified based on state-owned enterprises (SOEs) and non-SOEs; and IEs are measured from dimensions of factor markets (FM) and legal systems (LS).

Findings – First, the results show a negative relationship between CCC and firm performance. Second, the negative relationship between CCC and profitability is significant for non-SOEs but not for SOEs. Third, both the FM and LS strengthen the negative association between CCC and profitability. Fourth, the moderating effect of FMs and LSs is evident for non-SOEs only. The results hold when using alternative measures of WCM and profitability and while controlling for additional variables.

Originality/value – The current study shows that while WCM has a significant effect on the profitability of Chinese firms, such an effect greatly depends on the ownership structures and IE involved. The results thus offer important implications in helping the Chinese government create better IEs and in allowing manufacturing firms to improve upon their WCM practices.

Keywords Profitability, Working capital management, Ownership, Institutional environment, Cash conversion cycle

Paper type Research paper

1. Introduction

Working capital is involved in firms' daily operations, such as those related to procurement, production and sales, and it is cyclically invested in various areas such as in accounts payable, inventory, accounts receivable and so on (Richards and Laughlin, 1980; Wang and Yan, 2007). Working capital management (WCM) is thus essential to a firm's daily operations and corporate finances. According to the Ernst & Young report in 2015[1], global large pharmacy companies successfully reversed a decline in performance from 2007 to 2012 through improvements in WCM. Consistent with anecdotal evidence, prior empirical studies have documented positive effects of WCM on firm profitability (Jose *et al.*, 1996; Shin and Soenen, 1998; Deloof, 2003).

The unique environment in China makes WCM particularly important for Chinese listed firms. First, Chinese firms have limited access to long-term capital markets, suggesting that firms need to rely more on savings from WCM (Ding *et al.*, 2013). Second, China covers a vast territory with considerable diversity in regional institutional environments (IE). The IE, which applies a series of political, legal and social rules, greatly influences the allocation of

financial resources, costs of contracting, and thus firms' financial performance. Third, Chinese economy is characterized by the coexistence of both state-owned enterprises (SOEs) and non-SOEs. SOEs and non-SOEs differ in corporate missions, management mechanisms, financing abilities and operating efficiencies. All of these factors can affect the role of WCM on firm profitability.

Motivated by the importance of WCM for Chinese firms in such a unique setting, this paper examines IEs as an external factor shaping the relationship between WCM and profitability and whether this effect is influenced by ownership structures. We expect to find the IE to strengthen the association between WCM and profitability by improving the return on investment generated from cash savings of efficient WCM (Henisz, 2000; Chen *et al.*, 2015; Wang *et al.*, 2017). In addition, the effect of IEs should be more pronounced for non-SOEs, as their financial activities and returns on investment are more sensitive to cash savings generated from WCM (Hu *et al.*, 2006; Chen *et al.*, 2011; Chaney *et al.*, 2011; Boubakri *et al.*, 2012).

Following Jose *et al.* (1996) and Deloof (2003), we use the cash conversion cycle (CCC) to measure WCM, and we calculate CCC as days sales outstanding (DSO) plus days inventory outstanding (DIO) minus days payable outstanding (DPO). In addition, we measure IEs with an index for factor markets (FM) and legal systems (LS) developed by Wang *et al.* (2017), which is a widely recognized marketization index (Wang *et al.*, 2008; Chen *et al.*, 2011, 2015). In examining a sample of Chinese listed manufacturing firms obtained from the China Stock Market and Accounting Research Database (CSMAR) for 2010 to 2017, this paper documents the following findings. First, both FMs and LSs as proxies of IEs strengthen the negative association between CCC and profitability; second, the incremental effect of LSs and FMs on profitability is only evident for non-SOEs. Furthermore, our results are robust when using alternative measures of profitability and WCM and when including additional control variables in the model.

Our study makes several contributions to the literature. First, Hsieh and Wu (2013) find that ownership structures influence the relationship between WCM and the profitability of high- and mid-capitalization Chinese listed firms. We extend their findings by showing that in addition to ownership structures, the regional development of FMs and LSs influences the relationship between WCM and profitability. Due to China's unique IE, considerable variations in regional development are observed, thus highlighting a need to examine how such differences affect firm performance. Second, this paper is complementary to Singhania and Mehta (2017), who examine the WCM-profitability relationship across 11 countries. By using a regional index to examine the cross-sectional effects of a single country, we are able to measure different aspects of IEs and in turn avoid potential cross-country confounding effects (Wang *et al.*, 2008; Chen *et al.*, 2015). Third, the study combines IEs and ownership structures to examine their impacts on the associations between corporate WCM and corporate performance. Our findings suggest that the external IE is more important for non-SOEs, providing support for Ding *et al.* (2013), who propose that SOEs are not financially constrained. Finally, our results suggest that the Chinese government should develop policies to accelerate overall development of the country's IEs.

The structure of the paper is as follows. Section 2 proposes the theoretical framework and research hypotheses. Section 3 describes our data and methodology. Section 4 presents the empirical analysis. Section 5 presents the robustness check. Section 6 concludes the study.

2. Related literature and hypothesis development

2.1 Literature review

Working capital involves current assets and current liabilities and results from the time lag between the payment for purchases of productive resources and the recovery of cash inflows generated from product sales over the operating process (Richards and Laughlin, 1980; Shin and Soenen, 1998). The goal of WCM is to improve business performance, and the effectiveness of WCM should thus influence corporate profitability and liquidity (Shin and Soenen, 1998; Falope and Ajilore, 2009; Kong *et al.*, 2009).

Richards and Laughlin (1980, p. 34) argued that traditional measures of WCM, such as current ratio and quick ratio, fail to provide enough information on cash flow attributes of the transformation process, and a proper measure of WCM should thus recognize "the extent to which four basic activities – purchasing/production, sales, collection, and payment – create flows within the working capital accounts that are noninstantaneous and unsynchronized." They proposed the CCC calculated as DSO plus DIO minus DPO to capture the residual cash flow financing period. Since this innovation, many researchers have used CCC as a comprehensive measure of WCM to evaluate how WCM influences firm performance (Jose *et al.*, 1996; Deloof, 2003; Ding *et al.*, 2013; Ukaegbu, 2014; Singh *et al.*, 2017).

The effects of WCM on firm profitability are two-fold. On the one hand, increasing DSO, DIO and DPO can have positive effects on firm profits for several reasons. First, supplying trade credit to customers provides short-term financing to customers, allows for price discrimination, and serves as quality guarantees, which in turn leads to an increase in sales revenue (Brennan *et al.*, 1988; Long *et al.*, 1993). Second, large inventory stocks mitigate the likelihood of stock outs and allow for economies of scale (Blinder and Maccini, 1991; Fazzari and Petersen, 1993; Deloof and Jegers, 1996). Third, deferring payment to suppliers minimizes reliance on longer-term financing arrangements and the related interest expenses (Richards and Laughlin, 1980).

On the other hand, increasing DSO, DIO and DPO can have negative effects on profits. First, extending trade credit to customers and maintaining high inventory stock force firms to conserve additional reserves and to rely more on longer-term financing arrangements, which are associated with higher interest expenses and opportunity costs (Richards and Laughlin, 1980; Kieschnick *et al.*, 2013). Second, when asymmetric information between customers and firms is severe, this will increase bad debts and lower profits (Kong *et al.*, 2009). Third, maintaining high inventory stocks involves making additional expenditures on, for instance, warehouse rent, insurance and security (Baños-Caballero *et al.*, 2014). Fourth, deferring payment to suppliers forgoes the chance of taking the discount of earlier payments and increases the cost of goods sold (Raheman and Nasr, 2007).

Most prior studies document a significant negative correlation between CCC and firm performance. For example, Jose *et al.* (1996) found that lower CCC is associated with more profitability. Deloof (2003) investigated the relation between CCC and profitability for a sample of Belgian firms and documented a negative relationship between each component of CCC and firm profitability. Raheman and Nasr (2007), Kong *et al.* (2009) and Ukaegbu (2014) also found a negative association between CCC and profitability for Pakistani firms, Chinese listed firms and African firms, respectively. Furthermore, consistent with the view that CCC improves firm financial performance, Ding *et al.* (2013) find that for firms with low CCC, fixed capital investments are less sensitive to cash flow shocks.

In addition to CCC, scholars have proposed other measures of WCM. Gentry *et al.* (1990) proposed a weighted cash cycle while taking into account the implicit costs of cash outflows and inflows for different time points. However, Shin and Soenen (1998) argued that a weighted CCC is not needed when examining the relation between WCM and profitability. They proposed a variation of CCC and defined the net trade cycle (NTC) as accounts receivable plus inventory minus accounts payable multiplied by 365 and divided by sales, which captures "the number of 'days sales' the company has to finance its working capital under ceteris paribus conditions" (P38). While Shin and

Soenen (1998) found a negative association between NTC and profitability, Baños-Caballero *et al.* (2014) documented an inverted U-shaped relation between NTC and market to book value. More recently, Nobanee and Al Hajjar (2014) proposed the optimal cash conversion cycle (OCCC) to identify the optimal points of receivables, inventory and payables. Our paper contributes to this subset of literature by demonstrating that alternative measures of WCM provide consistent results for the association between WCM and operating performance.

Meanwhile, some scholars have begun to study the impact of internal and external factors on the association between WCM and firm performance. For example, Hsieh and Wu (2013) examine the ownership effect for a sample of large- and mid-cap Chinese firms for 2005–2011. They find that the relationship between CCC and profitability is weaker for firms exhibiting higher degrees of state ownership. Similarly, Ben-Nasr (2016) documented a differential effect of state and foreign ownership on the value-WCM relationship for a sample of 54 countries. He *et al.* (2017) investigated the WCM practices of listed Chinese firms before and after the adoption of the split share structure reform of 2005 and found that in the post-reform period, manufacturing firms significantly reduced their CCC and that such negative changes in CCC are associated with positive changes in firm performance. Singhania and Mehta (2017) also examine the effect of market dynamics on the WCM-profitability relationship based on data on 11 countries. We add to this subset of literature by providing evidence that the IE, in addition to firm ownership, significantly influence the relation between WCM and firm performance.

2.2 Hypothesis development

The studies presented above document a negative association between the CCC and profitability (Jose *et al.*, 1996; Deloof, 2003; Raheman and Nasr, 2007; Ukaegbu, 2014), suggesting that firms benefit from a shorter CCC which can either result from lowering financial costs or from pursuing more profitable investment opportunities.

Chinese firms exist in an IE characterized by considerable heterogeneity across regions. This IE, which applies a series of political, legal and social rules, greatly affects the development of the capital market and thus firms' financing and investment activities (Myers and Majluf, 1984). One well established theory on the effect of the IE is transaction cost theory, which proposes that social-political factors can reduce costs of bargaining, contracting, monitoring and enforcement and thus support a credible commitment to returns on investment (Henisz, 2000). Prior studies have documented the effect of IEs on Chinese firms' business performance. For example, Xia and Fang (2005) find that the IE mitigates the negative effect of governance control on firm value. Chen *et al.* (2015) find that a superior IE is associated with less IPO underpricing. However, the interesting question of how cross-sectional differences in the IE affect the WCM-profitability relationship remains unaddressed.

Following the prior literature (Wang *et al.*, 2008; Chen *et al.*, 2015), we examine levels of FM and LS development across localities in China. FM development involves the evaluation of the marketization of financial markets, the development of human resource markets and the marketization of technological achievements[2]. A stronger FM thus results in the more effective allocation of financial resources, in the involvement of more qualified professional experts and in more productive research expenditures, all of which improve firms' abilities to generate profits by shortening CCC.

Features of LS include the development of intermediary organizations, the extent to which legal environments are maintained, and the protection of intellectual property[3]. A sound LS ensures fair market competition and the legal rights of firms, shareholders and creditors (Wang *et al.*, 2017) and thus leads to reduced transaction costs and improved financial performance (Henisz, 2000; Chen *et al.*, 2015).

Therefore, firms operating under better FM and LS conditions are able to generate a higher return on investment and higher profits. We thus propose the following first hypothesis:

H1. A sound IE strengthens the negative relationship between WCM and profitability.

Our second hypothesis concerns the effect of ownership on the WCM-profitability relationship. Petersen and Rajan (1994) proposed that financing costs are greatly affected by the relationship between firms and creditors. In China, SOEs have strong political connections with the government, affording SOEs with high-quality resource and financial support (Shi, 2003; Wang, 2003). For example, SOEs can easily obtain loans from banks and waivers for enterprise liabilities (Cull and Xu, 2005; Chen *et al.*, 2011; Cull *et al.*, 2015). In addition, compared to non-SOEs, SOEs enjoy lower costs of debt and equity capital (Chaney *et al.*, 2011; Boubakri *et al.*, 2012). At the same time, SOEs emphasize both profitability and political objectives such as maintaining social stability (Liang *et al.*, 2015; Yang *et al.*, 2015), and their executives are evaluated through both firm profitability and political achievement. Social responsibilities such as those related to offering jobs increase SOEs' burdens and decrease SOEs' levels of operational efficiency and profitability (Wu, 2012).

On the other hand, most executives of non-SOEs are the founders or major shareholders of companies who emphasize long-term development and who exhibit stronger motivations to expand business operations and improve profitability (Chen *et al.*, 2011). Hu *et al.* (2006) found that compared to SOEs, non-SOEs are more productive and profitable.

Motivated by the unique characteristics of state ownership, the prior literature has examined how state ownership influences firm performance. For example, Chen *et al.* (2011) find that the sensitivity of investment expenditures to investment opportunities is weaker for SOEs in China, supporting their argument that ownership structures influence firm investment efficiency since SOEs help the government accomplish social and political goals. Ding *et al.* (2013) conclude that SOEs are not financially constrained as evidenced by the low sensitivity of fixed investments to cash flows.

While the above evidence suggests that SOEs have less financial constraints and may not operate as efficiently as non-SOE firms (Cull and Xu, 2005; Li and Jiang, 2006; Chen *et al.*, 2011; Ding *et al.*, 2013; Cull *et al.*, 2015), it remains unclear whether the ownership structure influences the effect of IE on the WCM-profitability relationship. Hsieh and Wu (2013) show that the WCM-profitability relationship weakens as levels of state ownership increase, suggesting that SOE profitability is less sensitive to WCM due to entrenchment effects and manager inefficiency. We thus expect to find that for SOEs, an improvement in the IE should not influence the WCM-profitability relationship since managers do not reinvest the savings generated from WCM efficiently.

However, for non-SOEs, the IE plays a more important role. Specifically, at the same CCC level, as the IE improves, non-SOEs can significantly increase their returns on investment and profits by adopting efficient investment practices and by lowering transaction costs. We thus expect to find the effect of IEs to differ among SOEs and non-SOEs. Stated formally, our second set of hypotheses is as follows:

H2a. The IE does not influence the relationship between WCM and profitability for SOEs.

H2b. The IE strengthens the relationship between WCM and profitability for non-SOEs.

3. Data and methodology

3.1 Sample and variables

Because we are interested in the relationship between WCM and firm performance after the financial crisis, we use data for the eight-year period of 2010–2017. Financial data on the listed companies examined in this paper mainly derive from the CSMAR. Data on the

FMs and LSs of each province are taken from the Marketization Index of China's Provinces: NERI Report 2016 (Wang *et al.*, 2017)[4]. We use manufacturing enterprises as our research sample because manufacturing enterprises account for a large proportion of all listed companies and engage in procurement, production and sales activities. To ensure the validity of the data, we exclude firms enjoying special treatment/particular transfers due to their abnormal financial performance. All variables are winsorized with the upper and lower 1 percent sample to minimize the influence of outliers (Aktas *et al.*, 2015). Our final sample for testing *H1* and *H2* covers 8,201 firm-years.

The dependent variable used in our study is firm performance. Qian and Zhang (2008) argue that under China's new accounting standards, core profits are a better measure of corporate performance. Following Penman and Zhang (2002) and Kong *et al.* (2009), we use the core profit margin of operating assets (*CorePR)* as a corporate performance indicator. As for manufacturing firms, profits are generated from operating assets; therefore, compared to other variables, the core profit margins of operating assets can serve as a better indicator of corporate performance. *CorePR* is calculated as:

$$\text{Core PR} = \frac{\text{Core Profit}}{\text{Operating Assets}} \times 100.$$

where Core Profit = Operating Income − Operating Costs − Cost of Sales − Business Taxes and Surcharges − Management Costs − Financial Costs and Operating Assets = Total Assets-Financial Assets. We also use the return on assets (ROA) as a proxy for firm performance as a robustness check.

Following most WCM studies (Joese *et al.*, 1996; Deloof, 2003; Lazaridis and Tryfonidis, 2006), we use CCC as our proxy for WCM. CCC equals DSO plus DIO minus DPO. As a robustness check, we also use the NTC (Shin and Soenen, 1998) as an indicator of WCM.

We use two measures of IE. One is the degree of FM development, and the other is level of LS development. Following prior literature (Wang *et al.*, 2008; Chen *et al.*, 2015; Ling and Wang, 2017; Yang *et al.*, 2015), we obtain data for FM and LS from the Marketization Index of China's Provinces: NERI Report (Wang *et al.*, 2017). The index for the FM includes three sub-indexes: financial industry development, human resource market development and the marketization of technological achievements. The LS index also includes three sub-indexes: the development of intermediary organizations, the extent of the legal environment and the protection of intellectual property. We also use nature of firm equity to identify whether a firm is an SOE or non-SOE.

Following Kong *et al.* (2009), we control for firm size, leverage and sales growth in our main model. Firm size has a significant impact on firm structures and corporate governance and then influences firm performance. Jose *et al.* (1996) also find that larger firms tend to pursue more profits and to adopt shorter cash cycles. Therefore, we use the logarithm of assets as an indicator of firm size (*SIZE*) to control the influence of scale on firm performance. Second, firm risks will have a significant influence on firm performance. We use financial leverage as a proxy for financial risk. DeAngelo and Masulis (1980) find that financial leverage always acts as a tax shield. For firms with less financial leverage, firm value will increase as financial leverage increases. Therefore, we control for the financial leverage (*LEV*) of firms to obtain robust conclusions[5]. Third, we use sales growth (*SGR*) to control the influence of growth on firm performance (Deloof, 2003). Table AI describes the specific variables used in this study.

3.2 Regression model

The following model is used to test *H1*. Because the sample includes financial data on different enterprises for multiple years, to control for individual effect differences of enterprises, a two-way fixed-effect regression (firm- and year-fixed) is used to analyze the studied relationship. The influence of the IE as a moderating variable of the relationship between WCM and firm performance is identified as β_3:

$$CorePR_{it} = \alpha + \beta_1 CCC_{it} + \beta_2 IE_{it} + \beta_3 CCC \times IE_{it} + \beta_4 SIZE_{it} + \beta_5 LEV_{it} + \beta_6 SGR_{it} + \varepsilon_{it}.$$

To test *H2a* and *H2b*, the sample is classified into SOEs and non-SOEs based on ownership to examine the combined effects of IEs and ownership on the relationship between WCM and firm performance.

4. Results

4.1 Descriptive statistics

The descriptive statistics and results of the Pearson correlation test are shown in Table I. In general, the core profit ratio is 4.261 percent for the sampled manufacturing firms. And the average sales growth rate is 17.6 percent, suggesting the listed manufacturing companies maintain a high sales growth rate. The average CCC is roughly 154 days.

Table I Panel B shows that *CorePR* is significantly negatively correlated with CCC at the 1 percent level. In addition, *CorePR* is significantly positively correlated with the sales growth rate (*SGR*) and with firm size (*SIZE*), which indicates that enterprises with more assets and high sales growth rates may enjoy better firm performance. *CorePR* is negatively correlated with financial leverage (*LEV*), indicating that the higher the degree of financial leverage, the lower a company's level of profitability.

The sample is then classified by ownership into SOE and non-SOE sub-groups as shown in Table II. As we can see from the table: the *CCC* of non-SOEs is 44 days longer than that of SOEs. The core profit margin of SOEs is 2.783 percent, which is lower than that of non-SOEs of approximately 5.123 percent. SOEs have higher levels of financial leverage, which shows

Table II. Descriptive statistics by groups

that SOEs receive more external funds. The t-test reveals differences in mean values of *CorePR* and *CCC* among SOEs and non-SOEs.

4.2 Regression results

Before testing *H1*, we first examine the relationship between CCC and firm performance and the effect of ownership structures to verify whether Hsien and Wu's (2013) findings hold for all of the listed manufacturing firms. The results are reported in Table III. Column (1) shows that firm performance is significantly negatively correlated with CCC, showing that a shorter CCC is conducive to improving corporate profitability. From Column (1) we know that when CCC is extended by ten days, the *CorePR* will decrease by 0.03. However, given that the mean core profits of manufacturing firms amount to 300m RMB, lengthening CCC by 1 day will cause core profits to decrease by approximately 900 thousand RMB assuming that the operating asset does not change. Columns (2) and (3) show the results for SOEs and non-SOEs, respectively. Altogether, we show that CCC, as a comprehensive indicator reflecting the efficiency of WCM, has a significant effect on the profitability of non-SOEs but not on that of SOEs, showing that when non-SOEs shorten their CCC, they can significantly increase their profitability.

Table IV shows the influence of IE on the main relationships, thus testing *H1*. Column (1) shows that the coefficient on the interaction between CCC and FM is significantly negative, indicating that a superior FM strengthens the relationship between WCM and firm

performance. Column (2) shows that the interaction term for CCC and LS is significantly negative, indicating that a stronger LS reinforces the relationship between WCM and firm performance. Altogether *H1* is supported when using both FMs and LSs as measures of the IE.

We then examine *H2a* and *H2b* based on ownership classifications and report the corresponding results in Table V. In Column (1) the coefficient on CCC is insignificant, suggesting that WCM has no effect on the profitability of SOEs. In addition, the interaction effect of SOEs' FM is negative but insignificant. As discussed above, a stronger FM supports a mature capital market and includes high-quality talent; a poorly developed FM presents the opposite characteristics. When SOEs operate in areas with advanced FMs, they can attract excellent employees and secure loans easily. SOEs operating in undeveloped FMs can also easily secure high-quality staff and loans due to resource endowments. Consequently, the FM has no effect on SOEs' relationships between WCM and profitability. In contrast, the FM strengthens the relationship between WCM and corporate performance for non-SOEs as shown in Column (2). In an area where the FM is well developed, non-SOEs are faced with fewer financing constraints and can attract higher quality talent, causing the FM to strengthen the relationship between WCM and firm performance for non-SOEs.

Table V. The impact of ownership, institutional environment on the relationship between WCM and firm performance

Consistent with the results found for FM, Columns (3) and (4) show that the coefficient of CCC×LS for SOEs is insignificant, while that for non-SOEs is significantly negative. The results indicate that non-SOEs operating under a sound LS can improve their performance more by shortening the *CCC* than those operating under a weak LS. Overall, the results in Table V support *H2a* and *H2b*.

5. Robustness tests

We conduct three robustness tests to verify whether our results hold. First, we use *ROA*[6] as a proxy of firm performance (Jose *et al.*, 1996; Shin and Soenen, 1998) and report the results in Table VI. The results for *H1* are presented in Columns (1) and (2) and show that the interaction terms of CCC×FM and CCC×LS are significantly negative. These results are consistent with the results given in Table IV. We then test the difference between SOEs and non-SOEs and present the results in Columns (3) to (6). Consistent with the results shown in Table V, we find that the interaction terms are only significant for non-SOEs. Therefore, the results for *H1* and *H2* hold when using alternative measures of profitability.

Second, we usethe NTC (Shin and Soenen, 1998; Nobanee and Al Hajjar, 2014) as a proxy of WCM. Though the Weighted Cash Conversion Cycle (WCCC) (Gentry *et al.*, 1990) and OCCC (Nobanee and Al Hajjar, 2014) can also be used to measure WCM, we are not able to measure OCCC or WCCC due to China's disclosure policies. We thus use NTC to conduct a robustness check and calculate it as follows[7]:

$$NTC = 360 \times (\text{Average Accounts Receivable} + \text{Average Inventory})/\text{Annual Net Sales}.$$

The results are shown in Table VII. We report the results for *H1* in Columns (1) and (2) and the results for *H2* in Columns (3) to (6). We consistently find significant negative coefficients for CCC×FM and CCC×LS for the whole sample and for the non-SOE sample, supporting *H1* and *H2*.

Finally, we apply other control variables based on the prior literature. The size of our sample is decreased after applying these additional control variables. For example, Deloof (2003) control for fixed financial assets and variability in net operating income, and Raheman and Nasr (2007) control for financial assets in the model. More recently, Ukaegbu (2014) controls for corporate governance while examining the effect of CCC on

Table VII. Robustness check 2: the relationship between NTC and firm performance

profits. Regarding fixed financial assets, Deloof (2003) argued that such assets are shares invested in other (mainly affiliated) firms to contribute to the firm that holds them, by establishing a lasting and specific relationship and loans that were granted with the same purpose. While we could not find fixed financial assets directly from financial statements, long-term equity investment satisfies this definition, and thus we use long-term equity investment as a proxy for fixed financial assets. The results are reported in Table VIII. Columns (1) and (2) presents the results derived when considering fixed financial assets (*Fixed_Fin*), financial assets (*Fin_Ratio*) and corporate governance (CG). Columns (1) and (2) show that the interaction terms of CCC×LS and CCC×FM are still significantly negative.

Following Deloof (2003), we include the variability in net operating income (Variability) in the model and calculate it as the three years variance of operating income/operating assets using a moving window. The interaction terms of CCC×LS and CCC×FM are still significantly negative, supporting our previous results.

6. Conclusion

From our analysis on the relationship between WCM and firm performance among China's listed manufacturing companies for 2010 to 2017, we document that CCC is significantly negatively correlated with profitability and that both ownership and institutional ownership play important roles in this effect. These results hold when using alternative measures of profitability and WCM. Our results have important implications for practice.

First, the CCC should be controlled within a reasonable range. Managers should develop a reasonable accounts receivable policy to prevent the emergence of bad debts which can decrease firm profit; shorten DIO to save warehouse costs; and accelerate accounts payables outstanding to establish good relationships with suppliers and to take advantage of sales discounts. Anecdotal evidence shows that many Chinese firms, such as Giant Group, Sanjiu Group and Delong Group, went bankrupt after running out of cash. Second, due to differences in resource endowments, governance mechanisms, and economic efficiency, SOEs and non-SOEs present different relationships between WCM and profitability. SOEs ought to reform executive selection and evaluation systems to mitigate agency problems and improve decision-making processes and bureaucratic environments. Third, the documented evidence showing that IEs strengthen the relationship for non-SOEs indicates

Table VIII. Robustness check 3: with more control variables that the government should accelerate marketization and create a fair and competitive marketplace for SOEs and non-SOEs.

This article analyzes the relationship between WCM and profitability under normal economic conditions and thus does not take economic crises into consideration. The conclusions presented can therefore not be extended to extreme events such as economic downturns. Further research may take the economic cycle into account when studying the effects of WCM on firm profitability.

Notes

1. *All Tied Up Working Capital Management Report 2015* published by Ernst & Young, www.slideshare.net/lesechos2/ey-all-tied-up-working-capital-management-2015.
2. The marketization of the financial market reflects the extent of market competition and the effectiveness of financial resource allocation. The human resource environment is evaluated as the availability of technicians, managerial staff and skilled workers. The marketization of technological achievements is the ratio of the trading volume of the technology market to the number of scientists.
3. The development of intermediary organizations is evaluated from services provided by lawyers, certified accountants and other industry associations. The legal environment of the market is measured as the fairness and efficiency of law enforcement, and the protection of intellectual property is the ratio of the number of approved patents to the number of scientists.
4. The latest data on factor market development and legal system environments are only recorded to 2014. We assume that factor market development and legal system environments did not change significantly after 2014 and following the extant literature (Wang *et al.*, 2008) the data on factor market development and legal system environments are kept constant for 2014 to 2017.
5. LEV = (Short-term Borrowings + Long-term Loans + Bonds Payable)/Total Assets. In the data set there are missing values for these three elements, and we remove an observation when any one of these three elements is missing. However, we apply an alternative treatment to the missing values by replacing all missing values with 0. After running the same regressions, the results remain robust.
6. ROA is another indicator commonly used as a proxy of firm performance. We also use ROE as a proxy of firm performance. The untabulated results show that our results hold when using this alternative performance measure.
7. However, under China's new accounting policies, *Net Sales* are not disclosed in financial statements. Therefore, we use *Sales* to replace *Net Sales* because the difference between *Net Sales* and *Sales* is not significant under China's new accounting policy.

Appendix

Type	Name	Abbr.	Description
Dependent variable	Core profit margins of operating assets	CorePR	Core profit/Operating Assets × 100
Independent variable	Cash conversion cycle	CCC	Days sales outstanding (DSO) + days inventory outstanding (DIO) − days payable outstanding (DPO), where DSO = 360/(credit sales/average accounts receivable); DPO = 360/(cost of goods sold/average accounts payable); and DIO = 360/(cost of goods sold/average inventories)
Moderating variables	Factor market Legal system	FM LS	The degree of factor market and intermediary organization development and the legal system index, both of which are selected from Wang *et al.* (2016) as an indicator of the institutional environments
Control variables	Firm size	SIZE	The logarithm of sales revenue
	Sales growth rate	SGR	Increase in operating income/total operating income for last year
	Financial leverage	LEV	(Short-term borrowing + long-term loans + bonds payable)/total assets
Other variables used for robustness tests	Return on assets	ROA	Net profit/total assets
	Return on equity	ROE	Net profit/equity
	Fixed financial asset	Fixed_Fin	Fixed financial assets/total assets
	Financial assets ratio	Fin_Ratio	Financial assets/total assets
	Corporate governance	CG	The number of board directors
	Net trade cycle	NTC	360 × (average accounts receivable + average inventory − average accounts payable)/annual net sales
	The variance in income ratio	Variability	The variance in operating income/operating assets for three years

Does corporate governance influence firm performance? Evidence from India[1]

Rupjyoti Saha[2], *Kailash Chandra Kabra*[3]

Abstract: Corporate Governance (CG) in India has undergone major transformation in the recent past with the enactment of Companies Act, 2013 and revision of SEBI's Listing Agreement. Though some studies were undertaken in the Indian context few conventional aspects of CG have been repetitively addressed with conflicting results. The aim of this study is to examine the impact of some prominent CG attributes such as board size, board independence, role duality, board's gender diversity, ownership concentration and audit committee independence on both market as well as accounting based measures of firm performance (FP). To this end the study uses a sample of top 100 non-financial and non-utility firms listed on the Bombay Stock Exchange (BSE) for the period of 2014-2018 and employs two stage least square with instrumental variables technique of estimation which takes into account potential endogeneity in CG-FP relationship. The findings reveal a significant positive impact of board size, ownership concentration and audit committee independence on market based measure of FP while board independence is found to have a significant negative impact on accounting based measure of FP. Moreover role duality and gender diversity are not associated with FP. The outcome of this study highlights how the relationship between CG and FP works in the unique institutional setting of India and it should be of interest to regulators, practitioners and other market participants.

Keywords: corporate governance attributes, firm performance, endogeneity, India.

JEL codes: G34, K200, O160.

Introduction

In the wake of major corporate collapses such as Enron, Worldcom, Tyco, etc. corporate governance (CG) has emerged as a widely debated topic around the globe (Letza & Sun, 2002). Initially research relating to various aspects of CG

[1] Article received 21 October 2019, accepted 29 November 2019.

[2] Department of Commerce, North-Eastern Hill University, Shillong (Meghalaya) – 793022, India, rupjyoti.1122@rediffmail.com, ORCID: https://orcid.org/0000-0002-5666-061X.

[3] Department of Commerce, North-Eastern Hill University, Shillong (Meghalaya) – 793022, India, ORCID: https://orcid.org/0000-0003-0635-2341.

remains confined to developed countries (Gompers, Ishii, & Metrick, 2003). However with the integration of world economies it has also been discussed in the context of some major emerging countries such as India due to a significant inclination among corporate to be listed in the international stock market. Following the landmark amelioration of the Indian economy through measures, such as Liberalization, Globalization and Privatization (LPG), a series of reforms have been initiated in order to raise the benchmark of Indian CG at par with the international standard. These regulatory initiatives have necessitated Indian companies to become more transparent and ethical in their operation so as to increase their likelihood of attracting long-term investment in the international capital market.

According to the dominant theoretical paradigm of CG, e.g., agency theory, a better-governed firm performs better because it calls for intensive monitoring of individualistic behaviour of managers (Jensen & Meckling, 1976). This perspective basically focuses on the conflict of interest that arises due to separation of ownership and management. While this type of agency problem is prevalent in developed countries emerging countries like India, characterised by a closely held family ownership structure experiences a different type of agency problem, e.g., controlling shareholders generally having their representation on board attempt to expropriate the wealth of minority shareholders. This unique agency framework raises a question about the effectiveness of major CG reforms in India as those measures are largely imported from governance codes of developed countries having a different institutional setting. Moreover though the existing CG framework in India is comparable with other developed countries its compliance in a true spirit by companies is doubtful due to dominance of family ownership.

In the light of major CG reforms in India over the past two decades several researchers have endeavoured to examine the effectiveness of these reforms in influencing the performance of firms. However some inadequacies are encountered in existing work such as Black and Khanna (2007) Balasubramanian, Black and Khanna (2010) which provide only cross sectional evidence on the relationship between CG and FP whereas, in case of other studies such as Jackling and Johl (2009); Arora and Sharma (2016), only some conventional facet of CG codes such as board size, board independence, role duality, ownership structure have been repetitively addressed with conflicting results. As pointed out by Arora and Sharma (2016) some qualitative aspects of the board such as inclusion of women directors, formation of an audit committee with independent directors have been largely ignored so far in the existing literature. Another important issue that remained overlooked is whether CG responds to FP (Arora & Bodhanwala, 2018) as Hermalin and Weisbach (1988) find that poor performance leads to improved CG mechanisms (eg: board independence) or firms with better performance may choose to adopt improved CG practices as a control mechanism to limit insiders to refrain from inefficient practices

(Denis & Sarin, 1999). Further, there could be some unobserved factors which may simultaneously determine both CG and FP (Hermalin & Weisbach, 2001). Though panel data regression models such as the fixed or random effect model control for unobserved heterogeneity, they are unable to handle simultaneity or reverse causality issue due to their core assumption of strict exogeneity. Thus considering CG variables as exogenous may show a spurious relationship with FP if the issue of simultaneity is not taken into consideration.

Against this backdrop the present study primarily aims to examine the relationship between CG and FP (both market based and accounting based performance) in the Indian context after taking into account the potential endogeneity in their relationship. Further, this study apart from considering the conventional CG mechanisms such as board size, board independence, role duality, ownership structure, also intends to examine the influence of board gender diversity and audit committee independence on FP.

The remaining part of the study is organized as follows: Section 1 presents an overview of CG in India; Section 2 reviews the theoretical and empirical literature and formulates different hypotheses. The methodology followed in the study including the selection of the sample, data used, measurement of variables employed are presented in Section 3; empirical results are discussed in Section 4; while final section provides the conclusions.

1. Corporate governance in India

Since the study is focussed on examining the impact of CG reforms on FP it is necessary to present an overview of CG in India over the past two and half decades. The first step towards corporate regulatory reform in India was initiated in 1991 with the adoption of LPG policy when it was forced to do so due to huge deficit in foreign exchange reserve. Following this a series of corporate scandals occurred in the early nineties which fuelled the need for good governance (Goswami, 2002). The most noteworthy event in the field of CG in the post-liberalization period was the establishment of Securities Exchange Board of India (SEBI) in 1992 as the regulator of the stock market. Subsequently SEBI set up several committees headed by some prominent industrialists such as Bajaj Committee in 1996, Kumar Mangalam Birla Committee in 1999; and Narayana Murthy Committee in 2003, in order to transform the CG scenario of India. In line with the Sarbanes-Oxley measures in the US the recommendations put forth by these committees specially focussed on independent directors, the audit committee, related party transactions, risk management, financial disclosures, shareholders' rights, etc. which were formally implemented through enactment of Clause 49 in the Listing Agreement. In conjunction with the initiatives of SEBI, the Department of Company Affairs and Ministry of Finance formed the Naresh Chandra Committee in 2002 and J.J Irani Committee in 2004, with the objective of reviewing the existing Companies Act, 1956 and this led to the introduction of new company bill in 2009. Regardless of these steps, yet again investors' confidence was shaken by the enormous fraud of information technology giant Satyam Computer Services Ltd in 2009, which was instigated by its chairman by presenting flawed books of accounts to its board, regulators and investors. This fraud cast doubt about directors' and auditors' independence as it is not possible to hide such facts without their involvement. Resultantly the Ministry of Corporate Affairs included several changes in the company bill 2009 on the basis of the report submitted by the Parliamentary Standing Committee on finance and overhauled the existing Companies Act 1956 through the enactment of the company bill in 2009 in the form of a new Companies Act, 2013 which received presidential assent on 29 th August, 2013. The Act established responsibility and accountability of independent directors and auditors, mandated the presence of a minimum of one women director on a board and prescribed additional disclosure norms such as a formal performance evaluation of directors, disclosure related to any change in the shareholding positions of promoters to the registrar of companies, etc. Further, to maintain parity with the provisions of the new act SEBI also revised its listing agreement (Clause 49) in 2014. In addition, most recently SEBI has replaced Clause 49 with Listing Obligations and Disclosure Requirements(LODR), Regulations 2015 in line with the OECD principles, which specifies more stringent rules as compared to Clause 49.

From the preceding discussion it is apparent that scope of CG requirements in India has been gradually expanded over the years in line with international practices. However it is often alleged that some prevalent features of Indian companies such as ownership concentration, existence of principal promoters, expropriation of minority shareholders' interests, poor disclosure practices, etc. have made them simply comply with the recurring imposition by different regulatory authorities rather than adopting the codes in real sense. Thus it is a prime need currently to examine the effectiveness of CG reforms in recent years in influencing FP.

2. Theory and hypotheses

Researchers have employed a number of theoretical perspectives in explaining the relationship between CG and FP. Among them agency theory has been most extensively used in governance research, which is premised on the inherent agency conflict between managers and owners, whereby managers with better access to information about firms are in a position to pursue some actions for their own interest at the expense of owners. It suggests the need for an adequate CG mechanism to protect owners from individualistic behaviour of managers, which in turn also maximizes the wealth of shareholders (Jensen & Meckling, 1976). On the contrary, the stewardship theory considers managers as stewards of firms' resources and they essentially act in the best interest of owners (Donaldson & Davis, 1991). Further, the resource dependency perspective consider managers as a crucial link between the firm and the key external resources required by it so as to have better FP. Based on the diverse theories and relevant literature, this section discusses some prominent CG attributes and their expected relationship with FP.

2.1. Board size

Determining ideal board size has been widely debated in literature which encompasses two aspects such as firstly, the coordination and communication issue created by board size, secondly, the monitoring capacity of the board to control the agency problem. Lipton and Lorsch (1992) opined that when board size increases it becomes difficult for board members to exchange meaningful ideas within the limited time available to them. Thus the cost associated with a large board outweighs its benefit and they suggested that an ideal board should include eight to nine members. Some empirical findings also support the view that large boards deteriorate FP as it becomes difficult to arrive at a consensus in time (Yermack, 1996; Mak & Kusnadi, 2005; Kao, Hodgkinson, & Jaafar, 2019). On the contrary proponents of the resource dependency perspective advocates that directors with a greater exposure to external settings assist firms in getting better access to various key resources, which in turn improves FP (Mizruchi & Stearns, 1988). Accordingly evidence, mostly from developing markets, reports the positive influence of board size on FP (Jackling & Johl, 2009; Sheikh, Wang, & Khan, 2013; Mishra & Kapil, 2018). They have highlighted some unique characteristics of the developing market such as a large proportion of family owned firms coupled with the scarcity of qualified outside directors whereby firms tend to restrict executive positions to family members, which limits the qualified pool of human resources. Thus in the Indian context the Companies Act, 2013, raised the maximum limit of directors to fifteen as compared to a maximum of twelve directors under the Companies Act 1956 and also simplified the procedure for raising the maximum limit, if the need arises and hence the following hypothesis can be framed: H_1: There is a positive association between board size and FP.

2.2. Board independence

Theoretically the agency perspective asserts that directors who work independently without any affiliation to the firm except for their directorship, are in a better position to diffuse the agency conflict that potentially leads to improved FP (Shleifer & Vishny, 1997) whereas the stewardship perspective contends that inside directors with better access to firms' information assist in taking prudent decisions which in turn leads to better FP. Empirical findings on this issue are mixed with studies reporting positive (Jermias, 2007; Jackling & Johl, 2009; Kao et al., 2019), negative (Muth & Donaldson, 1998; Singh & Gaur, 2009) and an insignificant influence of board independence on FP (Chang & Leng, 2004; Zabri, Ahmad, & Wah, 2016). From a practical standpoint, independent directors (IDs) started gaining prominence after the Sarbanes-Oxley Act mandated their presence on a board. Following the Anglo-American CG codes many developing countries including India mandated listed companies to have a minimum proportion of IDs on the board in order to have a better monitoring of corporate affairs. In this regard Singh and Gaur, (2009) contend that the contribution of IDs towards FP depends on the functions they perform in fulfilling their *monitoring* as well as *advisory* roles in a given context. In the case of a developed market such as the US, characterized by separation of ownership and control, the monitoring role of IDs is considered important in mitigating the agency conflict whereas in the context of an emerging market such as India, characterized by a highly concentrated family ownership structure, their monitoring role becomes less important due to owner—manager unification. However their advisory role in an emerging market becomes more important as firms often lack the requisite expertise needed to function (Khanna & Palepu, 1999) and thus their presence on the board can be expected to bring better resource expertise and it can be hypothesized that: H_2: There is a positive association between board independence and FP.

2.3. Role duality

Another important feature of the corporate board widely discussed in literature is its leadership structure. Proponents of the agency perspective suggest the separation of the role of CEO and chairman as this combined authority can lead to opportunistic behaviour which can have an adverse impact on FP (Jensen & Meckling, 1976). Moreover there is less possibility of detecting such behaviour when the same person occupies both the positions. Conversely, the stewardship perspective supports role duality as it offers greater autonomy to managers who act as stewards' in maximizing shareholders wealth (Donaldson & Davis, 1991). Given the diverse theoretical view empirical findings on the issue are mixed with studies reporting positive (Sheikh et al., 2013; Azeez, 2015; Mishra & Kapil, 2018), negative (Jermias, 2007; Kao et al., 2019) and no association (Chang & Leng, 2004; Tachiwou, 2016) between role duality and FP. Nevertheless CG codes around the globe as well as in India have emphasized the separation of the role of CEO and chairman in order to limit the power of board leaders (Cadbury, 1992; SEBI, 2015). Hence it can be anticipated that: H_3: There is a negative association between role duality and FP.

2.4. Gender diversity

The discussion of gender diversity on corporate boards primarily encompasses two significant propositions firstly, 'resource based perception' which contends that a gender diverse board brings diversity of opinions, external networks, set of leadership styles, etc. in managing corporate affairs (Carter, D'Souza, Simkins, & Simpson, 2010); secondly, 'diligence in monitoring' which asserts that female directors exhibit lower tolerance to opportunism than their male counterparts in decision making (Adams & Ferreira, 2009). Empirically studies document positive (Singh, Vinnicombe, & Johnson, 2001; Ntim, 2015), as well as no association (Carter, Simkins, & Simpson, 2003; Sanan, 2016) between board gender diversity and FP. In the Indian context, though, the Companies Act, 2013 mandated the presence of a minimum of one women director on the board. The uniqueness of family owned businesses necessitates the study as to whether such a gender quota actually impacts FP or is simply considered as mere formality. Nevertheless, based on the theoretical view and prevailing regulation, it can be hypothesized that: H_4: There is positive association between a board's gender diversity and FP.

2.5. Ownership concentration

Literature on ownership concentration draws attention toward two types of agency problem: firstly, the vertical agency problem or principal-agent conflict which mainly occurs due to the separation of ownership and control and secondly, the horizontal agency problem or principal-principal conflict, which arises due to a concentration of shareholdings above a certain level by few individuals or groups (Fama & Jensen, 1983). While the former is mostly prevalent in developed countries, emerging countries like India, characterized by a closely held family ownership structure, experiences the later. Though horizontal agency conflict (ownership concentration) is associated with some benefits such as: i) an efficient monitoring of management action as blockholders can influence management's decision by virtue of their position (Shleifer & Vishny, 1997); ii) elimination of the vertical agency problem as blockholders often also work as managers (Carney, 2005), and iii) an active involvement of the blockholders assists in maintaining the market value of the firm as they have a substantial investment at stake, it also creates some problems such as blockholders may pursue certain activities for their individual gain which may exploit the wealth of minority shareholders (e.g. increasing perquisites such as wasteful travel expenses). In the Indian context several CG codes were implemented in the past decades which focus on protecting the rights of minority shareholders. Accordingly, empirical evidence from India as well other emerging countries mostly shows a positive impact of ownership concentration on FP (Chang & Leng, 2004; Mak & Kusnadi, 2005; Singh & Gaur, 2009; Ducassy & Guyot, 2017; Kao et al., 2019) indicating that the benefits of ownership concentration outweigh its cost. Thus in the Indian context, it can be hypothesized that: H_5: There is a positive association between ownership concentration and FP.

2.6. Audit committee independence

Following the Sarbanes-Oxley Act in the US, the presence of an audit committee is globally recognized to maintain investors' confidence in financial markets. An audit committee is basically formed for the purpose of carrying out the audit process independently as it is entrusted with the responsibility of presenting an authentic picture of firms as revealed by their financial statements to the external auditor. It is unlikely to obtain such information from internal management whose very activities are being audited and thus the independence of the audit committee from internal management is necessary in order to maintain the objectivity and independence of external auditors which in turn also reduces the probability of fraud and encourages better performance (Klein, 2002). Empirically some studies report a positive association between audit committee independence and FP (Klein, 2002; Amar, 2014) whereas some studies reveal an insignificant association between the two (Chang and Leng, 2004; Qaiser & Abdullah, 2016; Berkman & Zuta, 2017). CG regulations in India require listed entities to set up an audit committee with a minimum of two thirds of independent members for the purpose of controlling manipulative reporting practices and to assess performance of companies and thus it can be hypothesized that: H_6: There is a positive association between audit committee independence and FP.

3. Methodology

This section presents selection of sample firms[4], data sources, variables measurement and construction of estimation models for examining the relationship between CG and FP.

3.1. Sample and data

The sample for this study comprises the top 100 non-financial and non-utility companies listed on the BSE based on market capitalization as on 31st March 2014. Financial and utility companies were excluded as additional regulations are applicable to them such as the Banking Regulation Act, 1949, the Electricity Act, 2003. The study covers a period of five years from 2013-14 to 2017-18, as this period is marked by some major CG reforms in India (i.e.: Companies Act, 2013, SEBI's Revised Clause 49, 2014, SEBI, Regulation, 2015). The 100 sam-

[4] The sample of firms' names can be provided upon request by the author.

ple companies selected in the initial year, e.g. 2013-2014 are studied over the consecutive years of the study. The necessary information regarding CG variables has been collected from annual reports of the respective companies and information relating to control variables and FP variables have been collected from the corporate database 'Capitaline plus'.

3.2. Variable measurement

3.2.1. Dependent variable

The resultant impact of CG on dependent variable e.g., FP is observed on both market based as well as accounting based measures of FP. In empirical models three proxies of FP such as: i) market capitalization (MCAP)—measured as the natural logarithm of market capitalization, ii) return on assets (ROA)—measured as the ratio of profit before interest and tax by total asset and iii) return on equity (ROE)—measured as the ratio of profit before interest and tax by equity share capital. All these variables have been considered as significant indicators of FP in literature (Arora & Sharma, 2016).

3.2.2. Independent variables

The details about measurement of independent variables included in the study such as board size, board independence, role duality, gender diversity, ownership concentration and audit committee independence are presented in Table 1.

Table 1. Measurement of independent variables

Acronym	Variables	Measurement
BS	Board Size	Total number of directors on board
BI	Board Independence	Percentage of Independent Non-Executive Directors(INDs) to total number of directors on board
RD	Role Duality	'1', if CEO is also the chairman of board, otherwise '0'
GD	Gender Diversity	Percentage of female directors to total number of directors on board
OC	Ownership Concentration	Percentage of shareholding by majority shareholders divided by total share capital
ACI	Audit Committee Independence	Percentage of Independent Non-Executive Directors to total number of directors in audit committee

Source: Own work based on literature.

3.2.3. Control variables

It is evident from prior work that FP is influenced by many other firm specific factors and accordingly this study employs some control variables which are generally considered to influence FP such as: i) firm size (Singh & Gaur, 2009; Sheikh et al., 2013), ii) firm age (Jackling & Johl, 2009; Arora & Sharma, 2016), iii) financial leverage (Sheikh et al., 2013; Arora & Bodhanwala, 2018), iv) Big-4 audit firms (Kao et al., 2019) and v) growth opportunities proxied by the research & development (R&D) ratio and advertisement ratio (Jackling & Johl, 2009). The details about measurement of control variables are presented in Table 2.

Table 2. Measurement of control variables

Acronym	Variables	Measurement
FSIZE	Firm Size	Natural logarithm of total sales
AGE	Firm Age	Natural logarithm of firm age since incorporation
LEV	Financial Leverage	Ratio of total debt by equity share capital and reserves
BIG4	Big4 Audit Firms	'1' for companies audited by BIG4 audit firms otherwise '0'
R&D	R&D ratio	Natural logarithm of R&D expenses by total sales
ADV	Advertisement ratio	Natural logarithm of advertisement expenses by total sales

Source: Own work based on literature.

3.3. Empirical model

A common approach for analyzing the relationship between CG and FP is to estimate the pooled OLS model (Klein, 1998). However in recent times one of the issues widely discussed in literature is the presence of endogeneity in the governance-performance relationship. There are some potential sources of endogeneity such as: unobserved heterogeneity (Hermalin & Weisbach, 2001) and simultaneity (Wintoki, Linck, & Netter, 2010). In presence of endogeneity the pooled OLS model may give biased and inefficient estimates as endogeneity violates its basic assumptions (Jackling & Johl, 2009). Further, some studies employ other panel estimation techniques such as the fixed or random effect models which handle the endogeneity issue in a partial manner as they only account for unobserved heterogeneity. Thus, to overcome this limitation, this study uses the Two Stage Least Squares (2SLS) with Instrumental Variables (IVs) estimation, which is widely considered as robust methodology to address the endogeneity issue. Moreover in this study a formal test of endogeneity such as the Hausmen Specification Test for all the CG variables has been conducted in the case of both market as well as accounting based measures of FP. In first step of the test CG variables have been regressed on all other exogenous variables. Subsequently the residuals for each CG variable is obtained from the first step which is further regressed on the ultimate dependent variable, i.e. MCAP, ROA and ROE whereby the result indicates that in the case of MCAP, co-efficient of residuals of BS, BI, ACI and OC are highly significant whereas in case of ROA and ROE, co-efficient of residuals of BI and OC are highly significant indicating the presence of endogeneity in respective cases (Gujarati, 2010). Hence the Hausmen test of endogeneity also advocates the application of 2SLS. The following equations have been used for estimation by applying 2SLS with IVs technique in order to examine the influence of different CG attributes on FP after controlling the influence of firm specific characteristics.

$$MCAP_{it} = \beta_o + \beta_1 BS_{it} + \beta_2 BI_{it} + \beta_3 RD_{it} + \beta_4 GD_{it} + \beta_5 OC_{it} + \beta_6 ACI_{it} + \beta_7 FSIZE_{it} + \\ + \beta_8 AGE_{it} + \beta_9 LEV_{it} + \beta_{10} BIG4_{it} + \beta_{11} R\&D_{it} + \beta_{12} ADV_{it} + \varepsilon_{it} \quad (1)$$

$$ROA_{it} = \beta_o + \beta_1 BS_{it} + \beta_2 BI_{it} + \beta_3 RD_{it} + \beta_4 GD_{it} + \beta_5\ OC_{it} + \beta_6 ACI_{it} + \beta_7 FSIZE_{it} + \\ + \beta_8 AGE_{it} + \beta_9 LEV_{it} + \beta_{10} BIG_{4it} + \beta_{11}\ R\&D_{it} + \beta_{12} ADV_{it} + \varepsilon_{it} \quad (2)$$

$$ROE_{it} = \beta_o + \beta_1 BS_{it} + \beta_2 BI_{it} + \beta_3 RD_{it} + \beta_4 GD_{it} + \beta_5 OC_{it} + \beta_6 ACI_{it} + \beta_7 FSIZE_{it} + \\ + \beta_8 AGE_{it} + \beta_9 LEV_{it} + \beta_{10} BIG_{4it} + \beta_{11} R\&D_{it} + \beta_{12} ADV_{it} + \varepsilon_{it} \quad (3)$$

where $\beta_0 \dots \beta_{12}$ are coefficients to be estimated; ε_{it} is a disturbance term; 'i' = 1, …, 100 sample firms; 't' = 2014-2018.

4. Empirical results

This section presents the descriptive statistics, correlation matrix and the regression results on the relationship between CG attributes and different measures of FP using 2SLS. The descriptive statistics of all variables included in this study are summarized in Table 3. Regarding CG attributes BS shows a range of 5 to 20 with a mean of 10.90, which is in conformity with the prevailing regulation except for one company (Larsen and Turbo Ltd.) where the maximum number of directors is twenty during two years of the study period. BI depicts a wide variation as the range is from 0 to 85.71 percent with a mean value of 50.58 percent. Though its average value is consistent with SEBI's listing agreement which requires the board to consist of a minimum 50% INDs when the board's chairman is an executive director, two sample companies (NLC Ltd. and MRPL Ltd.) did not have any INDs during two years of the study period. The mean value of RD indicates that 32 percent of sample firms have one person occupying both positions implying that the majority of sample firms (68 percent) have voluntarily separated the role of CEO and chairman. GD shows a mean of 12.41 percent while it was 5.3 percent in 2009 (Balasubramanian, 2013) indicating an enhanced participation of women on a corporate board. On average 84.51 percent of audit committees are occupied by INDs which is also consistent with SEBI (LODR) Regulations, 2015. In terms of OC the average percentage of shares owned by a majority shareholders is 91.66 percent indicating that sample firms have a highly concentrated ownership structure. FSIZE indicates less variation with mean and median values of 3.94 and 3.86 respectively while the age of sample firms shows a mean of 1.57 with a range of 0.84 to 2.05. Leverage gives a means of .31 with a range of 0 to 2.74 while the mean value of the Big4 indicates that only 35 percent of the sample firms are audited by Big4 audit firms. Sample firms' growth proxied by the natural logarithm of R&D ratio and advertisement ratio shows mean values of 0.18 and 0.04 respectively. The market based measure of FP, e.g. MCAP indicates mean and median values of 4.50 and 4.47 respectively which are 'reasonably' close indicating lesser variations among sample firms in terms of their market value while the accounting based measure of FP, e.g. ROA and ROE indicates wide variations as evident from their standard deviation values of 21.24 and 18.26 respectively.

Before undertaking the regression analysis multicollinearity among the independent variables is checked by using Pearson's correlation analysis. It is evident from the correlation matrix (Table 4) that multicollinearity is not a cause

Table 3. Descriptive statistics

Variables	Mean	Median	Standard deviation	Minimum	Maximum
BS	10.90	11	2.61	5	20
BI	50.58	50	12.36	0	85.71
RD	0.32	–	0.46	0	1

Source: Own calculations using STATA 14.

of concern in this study as the highest correlation coefficient is 0.481. The highest positive correlation ($r = 0.481$, $p < 0.01$) exists between BI and ACI as the percentage of INDs on the audit committee depends on the percentage of INDs on the board. This is followed by a significant negative correlation between OC and AGE ($r = -0.280$, $p < 0.01$). In addition RD is negatively related with BIG4 and ADV implying that firms having a combined leadership structure are less likely to be audited by Big4 audit firms ($r = -0.220$, $p < 0.01$) and they also have less advertisement intensity ($r = -0.262$, $p < 0.01$). Moreover, FSIZE and LEV are positively related ($r = 0.246$, $p < 0.01$) suggesting that large firms tend to have more debt in their capital structure. A robustness test for multicollenearity was done by calculating the Variance Inflation Factor (VIFs) for all independent variables and the highest VIF value obtained is 1.42 which is much below the threshold limit of 10 (Neter, Wasserman, & Kutner, 1989).

The result of 2SLS estimation is reported in Table 5. The results given in Column 3 are based on the market measure of FP e.g., MCAP whereas results presented in Columns 4 and 5 are based on accounting measures of FP such as ROA and ROE respectively. This section discusses the results pertaining to the impact of each CG attribute and control variables separately on the alternative measures of FP. Consistent with the expectation in H_1 the result reveals that BS is positively associated with MCAP at a one percent significant level though it is not significant in the case of ROA and ROE. This finding is parallel with Jackling & Johl (2009) suggesting that a large board brings a greater pool of expertise which in turn assists in boosting the overall performance of the firm. Contrary to the expectation in H_2, the result shows a negative impact BI on FP in the case of accounting based measures while its impact on market based measures is statistically insignificant. The negative impact of BI on operating performance of a firm is consistent with the findings of Jackling & Johl (2009), Singh & Gaur (2009) and supports the relevance of the stewardship perspective in India implying that as IDs are generally less aware of the internal strengths and weaknesses of the firm and thus their inputs in the decision making process have a negative impact on the accounting based measure of FP. Moreover, the insignificant impact of BI on MCAP highlights the lack of autonomy given to IDs due to the active participation of substantial owners in management whereby IDs are basically appointed to fulfill a statutory requirement while in the real sense they work under the dominance of blockholders. Regarding H_3, though its direction is negative, it is statistically insignificant at a conventional level in all the measures of FP. This insignificant impact of role duality on FP might be due to a limited demarcation among sample firms for this attribute to have statistical significance as 68% of them have voluntarily separated the role of CEO and chairman subsequent to the recommendation given by SEBI as well as various international bodies. The finding also exhibits the insignificant impact of a board's gender diversity on all measures of FP, discarding H_4. Though literature from developed markets establishes a significant positive

association between GD and FP (Singh et al., 2001; Ntim, 2015) this finding highlights the ramification of mandating women directors in the case of Indian companies as the dominance of family ownership leads to the appointment of female members of the promoters' family to executive management positions in order to comply with the existing regulation, even if they are unaware of the technicalities of business. Moreover in some cases where women directors are independent the prevailing scarcity of independent women directors with the right kind of expertise increases their engagement in terms of the number of board on which they serve and that in turn offsets their effectiveness. Further consistent with H_5 the finding indicates the significant positive influence of OC on market based measures of FP. This finding supports the result of Singh & Gaur, (2009) indicating that since blockholders have a substantial amount of investment at stake they undertake every possible action to maintain their investment value intact (Shleifer & Vishny, 1997). Nevertheless the result shows a negative relationship between OC and the accounting based measure of FP. Finally, H_6 can also be accepted as ACI is found to have a positive influence on market based measures of FP. This significance disappears when accounting based measures such as ROA or ROE are used as a dependent variable. Though the level of significance in the case of MCAP is weak such finding is important as it depicts the premium awarded by investors in terms of market value for having an independent audit committee. Regarding control variables FSIZE, BIG4, R&D and ADV are found to have a significant positive impact on FP whereas AGE and LEV have a significant negative impact on FP.

The observed *R*-square values and highly significant Wald-Chi Square values in all three models advocate of goodness of fit of the models. Moreover 2SLS may not bring better estimates than the panel data model if the selected instruments are incorrect. As discussed in earlier works the choice of appropriate instruments is challenging as it is difficult to obtain such instruments which are correlated with the endogenous regressors but not with the error terms (Kao et al., 2019). Following literature this paper uses one year lagged values of some CG variables like BS, BI, RD, ACI, OC as instruments in the case of model (1) and BS, BI and OC in case of model (2) and (3). Subsequently the appropriateness of the chosen instruments is examined based on two conditions. Firstly, relevance condition: the IVs should be correlated with the endogenous regressors which are examined through the test of weak instruments. Secondly, exclusion condition: the IVs should not be correlated with the error terms which are examined by the test of over-identifying restrictions. The result of the test of weak instruments specifies that the instruments are highly correlated with the endogenous regressors such as BS, BI, ACI and OC [Shea's Partial *R*-square = 0.56, 0.50, 0.38, 0.90] respectively in the case of model (1) and endogenous regressors such as BI and OC in the case of model (2) and (3) [Shea's Partial *R*-square = 0.53 and 0.90] respectively and therefore there is no weak instrument problem. Further, Sargan and Basmann statistics were calculated to test the exclusion condition whereby the insignificant value of Sargan chi-square and Basmann chi-square in all the models [shown in lower part of Table-5] suggests that IVs are not correlated with the error terms, thus implying that the chosen IVs are exogenous and valid.

Conclusions

This study examines the performance consequences of different firm level CG mechanisms in India. In particular the study focuses on the influence of prominent CG mechanisms such as- board size, board independence, role duality, gender diversity, ownership concentration and audit committee independence on different measures of FP for sample companies over a period of five years (2014-2018) using the 2SLS method of estimation. The result reports a significant positive impact of board size on FP whereas board independence is negatively associated with FP. Further the result also shows a significant positive impact of ownership concentration and audit committee independence on FP. Nevertheless role duality and gender diversity does not contribute significantly towards FP.

The results of this study have some important implications. Firstly, the positive association between board size and FP is congruent with the regulatory move of increasing the number of directors of the board and thus extending support for an implementation of the resource dependency theory in the Indian context. Secondly, the negative impact of board independence on FP suggests that the practitioners in the context of an emerging market the appointment of independent directors should not be viewed in terms of performance gains. However their existence can still be considered important in order to encourage ethical behaviour in the business. Thirdly, the positive influence of ownership concentration on FP indicates that blockholders are effective monitors and this is an encouraging sign for policy makers as the reforms initiated in India in the past two decades with a focus on protecting the interests of minority shareholders seem to be effective. Fourthly, the positive influence of audit committee independence on FP though weak, encourages the practitioners to comply with such a regulation as it significantly contributes to the maintenance of the confidence of investors. Finally, the result also suggests that merely having a gender diverse board does not suffice but that adopting them in a true spirit might worth trying.

This study has the potential to add some novelties to the existing literature. Firstly, it addresses the endogeneity issue of the CG-FP relationship in an emerging market by employing the 2SLS technique of estimation and also presents the additional tests for the justification of using the 2SLS technique. Secondly, departing from prior studies that are confined only to the conventional CG mechanisms, this study adds new findings with regard to the two noteworthy but least studied attributes of CG in the Indian context such as the board's gender diversity and audit committee independence. Finally, unlike prior studies where the impact of CG is mostly examined through the market based measure of FP this study shows the impact of different CG attributes on both the market as well as accounting based measures of FP.

This study has some limitations which also pave the way for future research such as: firstly, apart from the audit committee the Companies Act 2013 and SEBI (LODR), Regulation 2015, have also prescribed companies to form some other board committees in order to focus on specific areas and informed decision making which remains unexplored in this study. Future studies can emphasize this area by considering the other committees of a board such as a nomination and remuneration committee, stakeholder relationship committee, corporate social responsibility committee and risk management committee so as to find their possible impact on FP. Secondly, some unique characteristics of family owned business in India such as the number of promoters on the board, family members on the board, etc. could constitute a useful extension of analysis in future studies. Finally, some other qualitative aspects such as the expertise of female directors on the board, the expertise of independent directors included on the audit committee might have a significant contribution towards FP and thus could be usefully considered in future studies.

Keywords: Changes in accounting policies, Market Share Price, Relationship, Empirical Research

Abstract. In the increasingly complex and intense competition of modern society, enterprises in order to survive, in its business process will use a variety of ways to ensure that their own business results to meet the requirements of investors and related interest groups to achieve the purpose of continuing operations, but also That is, through various means to beautify the financial report. With the continuous strengthening of supervision, enterprises began to transfer related party transactions to the accounting policy, that is, changes in accounting policies. The effectiveness of the market that the effective capital market should be the center of all kinds of information integration, the market will absorb the information reflected in the stock of the enterprise. In this paper, by using the event study method, through the 2013 annual report disclosed in the accounting policy changes of listed companies as a sample, to discuss the impact of changes in accounting policy on the stock price.

1. Introduction

During Deng Xiaoping's period, China began its economic policy of reform and development. The implementation of the policy has brought our country from planned economy to market economy, and the market guided enterprises and the people to spontaneously start with the development and growth of capital economy. The two stock exchanges founded later have become the official symbol of the burgeoning of China's capital market. The increasingly improved supervision mechanism has made our capital market more standardized and orderly. The split share reform implemented in 2005 has made the stock market of our country move towards the international market. The rapid economic development has made the stock market play an increasingly important role in our financial system. With the development of economy in the past 20 years, China's influence in the securities market has become growingly profound and lasting. Nowadays, as an important part of China's economic development, the securities market is gradually stepping among our common people, and its influence is also going up.

Owing to the special nature of the securities market, the securities market has attracted great attention from the capital. The high attention paid to information in the securities market is the performance of its high sensitivity to the market. The complexity of the stock market determines that all the factors that exist in the stock market may impact the changes of the stock price. Complex relations and factors keep the stock market in a constant fluctuation. Meanwhile, the price of stocks is also influenced by these complex factors, which are changing all the time.

In comparison with the foreign markets, the development of China's capital market is still very immature, and the relevant policies and management are still incomplete. There is still a large amount of real or false information in China's securities market, which is always concerned by the investors of enterprises and influences their subsequent investment plans. The new accounting standard promulgated in 2006 has provided the greater room for enterprises to choose accounting policy to a certain extent. The accounting policy adopted by enterprises according to specific circumstances does not only have an impact on the profits of enterprises, but also has a certain impact on the operation decision and direction of strategy of the enterprises in the later period. As for the investors, the expected future returns and operating conditions of enterprises are factors that need to be carefully considered, thus they will also have an impact on investors' investment behaviors, and the corresponding investor's investment behaviors are reflected in the fluctuation of stock price. Therefore, it is a necessity to study the impact of the accounting policy changes on the fluctuations of stock prices of the listed companies.

2. Literature review

Hupphorn (1953) puts forward that the main purpose of the manager of the enterprise is to balance the yield returns of different periods, rather than maximizing the reported profits, which also has brought forward new idea for the later research. Then Watts and Zimmer came up with three famous hypotheses in the study of the reasons for accounting policy choice, i.e. bonus plan, political cost and debt contract. In 1985, Healy's study found that if profit volumes fluctuate around the targeted earnings, the managers may take actions to increase their earnings during the reporting period; on the contrary, the managers will reduce their earnings during the reporting period, i.e. the details of the bonus plan play an important role in judging the impact of the bonus plan of the enterprise on accounting behavior, whilst well verifies the hypothesis of the bonus plan.

There are lots of studies on the motivation of changes in accounting policies in China. Yang Peng (2011) discusses that the audit of internal control of enterprises will influence the change of accounting policies of the enterprises, in which the regression method is applied to test the influence of internal control of enterprises on the change of accounting policies, and the factors that influence accounting policies are considered from the perspective of enterprises. Hu Liya (2015) puts forward the enterprise financial statements under the background of the change of accounting policy of the enterprise. In her analysis of the enterprise financial statements, the special impact of the change of accounting policy is focused on and then the targeted analysis and research are made on the change of the accounting policy of the enterprise. Zhang Xialian (2015) interprets the primary cause of the changes of accounting policy in enterprises as their pursuit of the maximization of the benefits, and the way enterprises take advantage of is the information asymmetry between the enterprises and investors when discussing the causes and effects of the changes of accounting policy in enterprises, Without doubt, some scholars try to use different ways to establish new theories or to explore the behavioral motives of the change of accounting policy from the new perspectives.

3. Overview of basic theory

3.1 Efficient market hypothesis

Eugene Farea, an American financier, put forward the efficient market hypothesis in the 1960s. He believed that the stock price of the market could not be predicted, which has been verified by that the market value follows the random walk model. The stock price of an enterprise is influenced by the demand of investors, and the demand of investors is mainly reflected by the accounting information issued by the enterprise. The change of accounting policy may or may not have an impact on the accounting profit of the enterprise. But the investors in the market will not care about the "past" accounting information of the enterprise, and they are more concerned about the profits the enterprise can bring to them. Therefore, only when the change of accounting policy the enterprise that affects the future earnings of the enterprise, i.e. the future cash flow and cash dividends of the enterprise, the investors will decide whether to buy stocks or not according to the degree of influence, which will also have an impact on the stock price.

3.2 Asymmetric information theory

Due to the characteristics of information generation and dissemination, there often exist the distortions and misunderstandings in the process of information transmission. In the securities market, since the status of the interested parties of the information differs in receiving and using, the corresponding information they receive is asymmetric, and the information the buyers and sellers possessing differs. The more the authenticity and quantity of the information become, the more accurate the analytical judgment will be. In reality, this information asymmetry extensively exists. As for an enterprise, retaining more relevant information will make the investors not know the real situation of the enterprise, and the enterprise will have more commanding heights to gain more benefits. Therefore, there exist the behaviors that the enterprises use information asymmetry to make their statements accepted by the investors and relevant groups.

3.3 Enterprise contract theory

The goal of the enterprise comes from the relevant requirements of different contractors. For instance, the requirement of shareholders for the enterprise is the maintenance and appreciation of the value of the capital; the creditors of the enterprise are concerned about whether the enterprise can repay the principal and interest at maturity, etc. The requirements of the relevant contractors affect the operation of the enterprise, and the contractors are rational investors. They will choose whether to join or withdraw from the contract according to their own costs and benefits and their withdrawal will have an impact on the enterprise. The investors' consideration of the enterprise also comes from the accounting information issued by the enterprise. When the management chooses the change of the accounting policy, different accounting policies will lead to different accounting information, so as to influence the degree of investors' recognition of the enterprise.

4. Research method and hypothesis

4.1 Research method

Event study is based on the hypothesis of market efficiency, which is used to discuss the impact of a specific event on the stock price of the enterprise. This paper examines the impact of the change of accounting policy on the stock price by the virtue of event study. Firstly, a reasonable sample for the change of accounting policy should be selected, and the data of stock price before and after the event of the sample company should be possessed. Secondly, the normal and abnormal rate of return of stock price and the effective rate of return of stock price should be calculated by substituting the market model in. By comparing the abnormal rate of returns and zero, whether the change of accounting policy of the enterprise has exerted Influence on the stock price or not can be worked out.

When discussing the relationship between the change of accounting policy and stock price in event study, the abnormal rate of return should be firstly determined.

To calculate abnormal rate of return during the event period should firstly calculate the expected normal rate of return of the enterprise, which is estimated by applying the market model in the paper, namely:

$$R_{it} = \alpha_i + \beta_i * R_{mt} + \varepsilon_{it} \quad (1)$$

of which, $E[\varepsilon_{it}]=0$ and $Var[\varepsilon_{it}]=\sigma_{it}^2$

R_{it} is the rate of return of the stock i on the t day. In this paper, the daily rate of return of cash dividend of the sample company on the t day is taken as the daily rate of return of the day; R_{mt} is the market rate of return on the t day of the enterprises and the α_i and β_i are the parameters to be estimated. Taking the annual report date of the sample company as the midpoint, the stock data of [-30, 30] are used. Finally, the normal rate of return of each company's stock price during the window period is calculated based on the estimated α_i and β_i.

Secondly, the daily abnormal rate of return of each stock during the window period is calculated.

$$\mathrm{AR_{it}} = \mathrm{R_{it}} \cdot \quad (2)$$

AR_{it} denotes the abnormal rate of return of the stock i on the t day; $\bar{R}_{it}$ is the normal rate of return of the stock i on the t day estimated under the market model; R_{it} is the effective rate of return of the stock i on the t day.

Finally, there are daily average abnormal rates of return of some stocks during the window period.

$$\mathrm{AAR} = \frac{1}{N}\sum_{t=1}^{N} \mathrm{A\,R_{it}} \quad (3)$$

N is the number of samples.

4.2 The proposition of hypothesis

In the complex economic activities, there are many factors affecting the stock price of the enterprise. From the information perspective, the external accounting information of the enterprise will affect the investment action of the investors in the enterprises. For investors, when the company is in a profitable state, they will invest, and the stock price will rise. Contrarily, they may withdraw the investment and the stock price will decline. On the premise of the market efficiency hypothesis, the accounting behavior of the enterprise will affect the change of stock price. The change of accounting policy of an enterprise is related to its operating income, i.e. the change of accounting policy of an enterprise will have a certain impact on the stock price of an enterprise. Therefore, the hypothesis is put forward.

Hypothesis 1: The change of accounting policy has an effect on stock price, i.e. the abnormal rate of return is not zero.

Hypothesis 2: The impact of the change of accounting policy on the stock price of the listed company differs before and after the window period.

5. Empirical results and analysis

5.1 The analysis of abnormal return of rate

Figure 5-1 shows the connection diagram of abnormal rate of return from t_{-10} to t_{10} . It can be seen intuitively that the average abnormal rate of return of other days show a downward trend except for the -10 day on which the average abnormal rate of return is higher. Table 5-1 lists the abnormal rates of return during the window period. It can be seen that the abnormal rate of return of 21 days are not zero except for the 2nd and 6th days, which indicates that the event has an impact on the stock price. This result is cross-checked with hypothesis 1. The average abnormal rates of return of the - 8, - 3, 0, 5, 7 and 10 day is negative and those of the other days are positive. The average abnormal rate of return on the event day is - 0.35%. The reason may be that some investors leave the market after a good turn, which makes them turn to be negative. In the following three days, the abnormal rate of return is respectively 0.12%, 0.10% and 0.13% to compensate for the negative value before, i.e. some investors join in the investment, which leads to the sustained rise of the stock price. It is demonstrated that the impact of the change of accounting policy on the stock price is short-term, which will be digested by the market in a short time.

Table 5-1 Abnormal rate of return of the event window

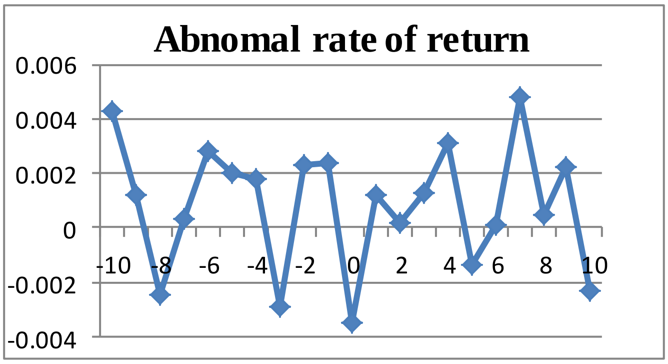

Fig. 5-1 Abnormal rate of return during the window period

5.2 The analysis of cumulative abnormal return

As can be seen from Figure 5-2, the cumulative abnormal rate of return during the window period shows a distinct upward trend; after the seventh day of the event, the cumulative abnormal rate of return shows a distinct upward trend.

Except for the 9th and 10th days, the cumulative abnormal rate of return slightly decreases. In Table 5-2, it can be seen that in 21 days during the window period, except the - 9, - 8, - 5, - 4 day, the other abnormal rates of return are obviously not zero, the abnormal rates of return of the - 10, - 9 day are negative, and those of other days are positive.

5.3 The analysis of the business performance of the enterprise

Through the impact of the change of accounting policy on the profit of the enterprise, the profit is divided into two groups: rising and falling. According to the chart of abnormal rate of return, it can be concluded from Figure 5-3, Figure 5-4 and Figure 5-5 that as for the cumulative abnormal rate of return on the event day [-10, 4], the increase of profit is higher than the decrease of profit; as for the cumulative abnormal rate of return on the event day [-20-20], and the increase of profit is lower than the decrease of profit. This shows that the impact of accounting policy on the profits of listed companies during the different periods is different. There are some differences before and after the event of the change of accounting policy, which is consistent with hypothesis 2.

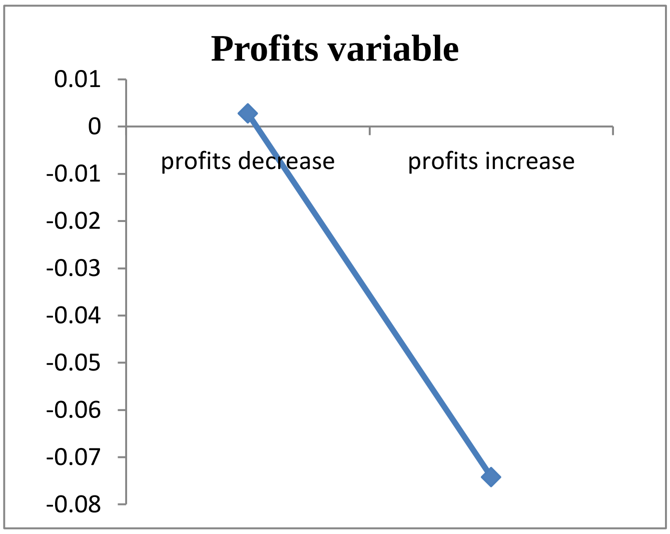

Fig. 5-3 Abnormal rate of return on the event day

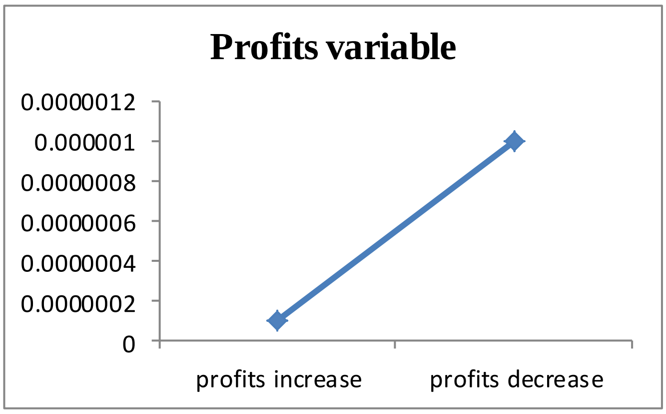

Fig. 5-4[-10, 4] Abnormal rate of return

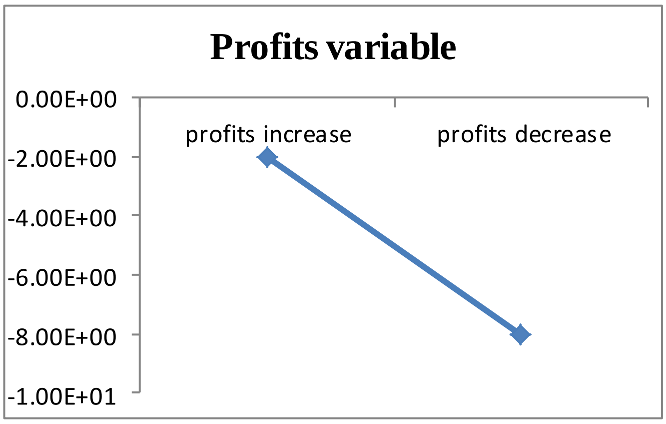

Fig. 5-5 [-20, 20] Abnormal rate of return

6. Research results

This paper uses the event study to study the change of the stock price of the listed company before and after the change of the accounting policy in 2016, and comes to a conclusion:

The market responds fairly to the change of accounting policy. The efficiency of the market considers that the securities market responds to the disclosure of accounting information by the enterprise, which is reflected in the stock price of the enterprise, i.e. the stock price will fluctuate with the disclosure of accounting policy information.

In the short run, the impact of the change of accounting policy on the stock price is limited, which will be absorbed by the market in a relatively short period of time. All abnormal returns obtained through the change of accounting policy will not last long.

As for the impact of the change of the accounting policy, it differs in the early and late stage of the event from the profit of the enterprise.

Abstract

We investigate whether increased investor demand for financial information arising from higher market uncertainty leads to greater media coverage of earnings announcements. We also investigate whether greater coverage during times of higher uncertainty further destabilizes financial markets because of greater attention-based trading or, alternatively, improves trading and pricing by lowering investor acquisition and interpretation costs. When uncertainty is higher, we find evidence of greater media coverage of earnings announcements and that the greater coverage leads to improvements in investor informedness, information asymmetry, and intraperiod price timeliness, and greater trade by both retail and institutional investors. In contrast to the media serving an expanded role in improving capital markets during more uncertain times, we fail to find that changes in firm-initiated disclosures lead to similar improvements and find that less frequent analyst forecast revisions exacerbate problems in capital markets during earnings announcements.

1. Introduction

Investors face significant challenges in gathering information about firms' expected future payoffs. As evidence of these challenges, prior research demonstrates that investors are affected by the coverage of earnings information through the media, social networks, equity and credit analyst reports, and other intermediaries (e.g., Blankespoor et al., 2013; Bushee et al., 2010; De Franco et al., 2009; Drake et al., 2017; Huang et al., 2014).[3] These studies find evidence of important capital market benefits of greater coverage of earnings information—such as narrower spreads, increased liquidity, and reduced mispricing. Underlying these studies is the notion that investors are constrained in their ability to obtain news or that intermediaries' reports and stories provide additional information beyond firms' earnings releases. Such constraints can arise because investors do not pay the significant costs to be directly informed or have limited cognitive resources to pay attention (e.g., Hong and Stein, 1999; Merton, 1987). Information intermediaries can mitigate these constraints. Greater coverage by intermediaries, however, can also lead to greater problems in financial markets, such as attention-driven trading and momentum trading (e.g., Barber and Odean, 2008).

This study examines whether periods of increased market uncertainty lead the media to expand its role as an intermediary of earnings announcements. We investigate whether higher market-wide investor uncertainty leads to an outward shift in investor demand for financial information that manifests itself through greater media coverage of earnings announcements. Because investors are averse to uncertainty (e.g., Bansal and Yaron, 2004; Drechsler, 2013), their aggregate demand for financial information can grow when market uncertainty increases. We predict an expanded role for the media because it is an information intermediary with extensive readership and broad coverage and one that specializes in the production of relatively low-cost news reports. Because of extensive readership, the production costs of creating stories can be spread more easily across subscribers, leading to lower average costs for producing stories and potential greater profitability. Because of broad market coverage and relatively low production costs, the media can respond to increased demand with an expansion in coverage. We further predict that the media will shift their coverage increasingly to earnings announcements rather than non-earnings announcements because earnings

[3] Miller and Skinner (2015) provides a discussion of recent developments in this line of research.

releases have low acquisition costs, are predictable, and typically contain value-relevant information that can help market participants resolve uncertainty. Whether the media shifts coverage based on the level of market uncertainty is unclear, as such actions involve the costly reallocation of resources and higher uncertainty can make it more difficult for media stories to affect investor opinions.

This study also examines how greater media coverage of earnings announcements influences trading and pricing during periods of higher market uncertainty. During such times, increased media coverage of earnings announcements can lead to improved trading and pricing, as evidenced by lower mispricing and information asymmetry, and greater speed of price discovery (e.g., Bushee et al., 2010). However, whether this occurs is unclear, as in other settings, prior research finds that greater media coverage can reduce price efficiency because of resulting attention-driven trading (e.g., Barber and Odean, 2008) and momentum trading (e.g., Hillert et al., 2014), and because of slanted media coverage of news (e.g., Gurun and Butler, 2012).

Using media stories from the RavenPack database during 2004–2013 and the Chicago Board Options Exchange's Volatility Index (VIX) to measure overall market uncertainty,[4] we find that media coverage of earnings announcements increases during periods of higher market uncertainty and that the increased coverage leads to improved trading and price efficiency at earnings announcements.[5] In contrast, we find that media coverage during non-earnings announcement periods decreases with the level of market uncertainty. As higher market uncertainty can lead to important changes in the supply of information by other market participants, which can in turn affect the coverage decisions of the media, our analysis also examines how concurrent changes in firm-initiated disclosure and financial analyst forecasting behavior affect the change in media coverage. During earnings announcements, we find that higher uncertainty leads to less frequent analyst revisions but fail to find a change in firm-initiated disclosures. The decline in analyst revisions, in turn, leads to lower media coverage during periods of greater uncertainty. In contrast, outside of earnings announce-

[4]We focus on the VIX because it captures investors' expectations about future volatility, is widely followed by market participants, especially the media, and affects the broadest set of listed firms. For instance, the index is often colloquially referred to as "Wall Street's fear gauge" and as "a staple of the financial press" (Loder and Banerji, 2017). The focus on the market's expectation differs from alternative measures of expected future macroeconomic uncertainty (Jurado et al., 2015; Rossi and Sekhposyan, 2015). Other types of common uncertainty (e.g., industry uncertainty) can lead to similar problems for investors.

[5]Price efficiency is defined generally as the extent to which prices and trading capture all information available to market participants.

ments, we find that higher uncertainty leads to relatively fewer firm disclosures but relatively more frequent analyst revisions, which, in turn, result in lower and higher media coverage, respectively.

In further analyses, we provide evidence of when and how the media makes systematic coverage changes during periods of higher market uncertainty. We find greater media coverage when market uncertainty increases for each VIX quartile, suggesting that the media monitors and responds to user demand for financial information at different levels of the VIX. We also find that economic policy uncertainty (Baker et al., 2016), foreign currency volatility, and other sources of market uncertainty are important drivers of the VIX that lead to greater media coverage of earnings announcements. In addition, we show that the lower media coverage found during non-earnings announcement periods is largely explained by the greater coverage of other firms' earnings releases, consistent with non-earnings announcement coverage being crowded out during periods of higher uncertainty. Finally, we show that the media shifts coverage towards short news flash stories that can quickly rebroadcast disclosures, towards bellwether firms (i.e., firms whose earnings are most closely linked to the macroeconomy), away from full stories, and less towards non-bellwether firms.

Regarding how greater coverage at earnings announcements during periods of higher market uncertainty affects capital markets, we find that the greater coverage leads to improvements in trading and pricing. Overall, we find that higher market uncertainty leads to deteriorating capital market conditions at earnings announcements, as evidenced by abnormally higher price changes and trading volume, wider bid-ask spreads, lower depth, reduced intraperiod price timeliness, and increased trade by retail investors but decreased trade by institutional investors. When we focus on how the level of the VIX affects media coverage and then how media coverage affects these capital market outcomes, however, we find that the greater coverage during such times leads to improved investor informedness, as evidenced by higher abnormal price changes and trading volume. We also find improved price efficiency, as evidenced by narrower spreads and greater depth, increased intraperiod price timeliness, and increased trade by not only retail investors but also institutional investors. In addition, when we focus on how the level of the VIX influences firm disclosure and analyst forecast revisions and then how each affects the different capital market outcomes, we find that fewer analyst forecasting revisions during earnings announcements lead to even worse capital market outcomes but that disclosure changes have little impact on capital market outcomes.

These findings offer several important contributions to prior literature. We provide evidence that media coverage increases at earnings announcements during periods of elevated market uncertainty and that the increased coverage in turn leads to improved trading and pricing. This evidence builds on and extends the growing body of research findings of when and in what settings media coverage can make capital markets more or less efficient (e.g., Blankespoor et al., 2018).

In addition, we provide evidence of how the media makes trade-offs during times of higher uncertainty. Prior research shows that media attention clusters around earnings announcements (e.g., Tetlock et al., 2008), however, little evidence exists regarding why that coverage changes over time or across firms. Our results provide evidence that the media's move to expand coverage of earnings announcements crowds out the coverage of non-earnings announcement periods. Our results also provide evidence that journalists write fewer full stories during periods of higher uncertainty but move to more frequent small updates using short news flashes. Further, our results provide evidence of increased coverage of bellwether firms while not increasing coverage as much for non-bellwether firms.

Finally, our findings demonstrate that the importance of media coverage during earnings announcements grows during times of higher market uncertainty relative to other sources of information. In particular, during such times, we find that firm-initiated disclosure is relatively unchanged and that analyst forecast revisions are less frequent at earnings announcements. In addition, in contrast to the activities of the media improving capital market outcomes at earnings announcements, we fail to find similar evidence for firm-initiated disclosures and find that less frequent analyst forecast revisions result in worse capital market outcomes.

2. Background and research hypotheses

2.1. Prior research on the media and earnings announcements

The media plays an influential role as an information intermediary in financial markets.[6] Coverage by the media tends to concentrate on firms that are of greater interest to its readers, individuals, and institutional investors. This leads to greater coverage for larger firms, value stocks, firms with

[6] A large literature examines the role of the media in financial markets: Ahern and Sosyura (2014); Ahn et al. (2019); Blankespoor et al. (2018); Bushee et al. (2010, 2018); Bushman et al. (2017); Drake et al. (2014, 2017); Engelberg and Parsons (2011); Fang et al. (2014); Fang and Peress (2009); Griffin et al. (2011); Guest (2018); Hillert et al. (2014); Klibanoff et al. (1998); Miller (2006); Peress (2014); Solomon (2012); Solomon et al. (2014); Soltes (2011); Tetlock (2007); Tetlock et al. (2008); Tetlock (2010); Thompson et al. (1987); Twedt (2015).

more analyst coverage, firms more widely held by individuals and institutions, greater idiosyncratic volatility stocks, indexed firms, firms with more employees, more heavily traded stocks, and momentum stocks (e.g., Bushee et al., 2010; Drake et al., 2014, 2017; Fang and Peress, 2009; Hillert et al., 2014). Coverage by the media also tends to concentrate during the days around earnings announcements (e.g., Drake et al., 2014; Tetlock et al., 2008; Thompson et al., 1987). Accordingly, the media appears to respond to the demands of individual and institutional investors to follow certain types of firms and to cover earnings releases to meet investor demands.

Media coverage of earnings announcements also has important capital market consequences. For instance, Bushee et al. (2010) finds that media coverage of earnings announcements assists in narrowing bid-ask spreads and increasing depth. Soltes (2011) also finds that greater coverage of earnings information increases trading volume and lowers idiosyncratic volatility. Engelberg and Parsons (2011) shows that local coverage of earnings announcements leads to greater trading by local investors. Drake et al. (2014) demonstrates that cash flow mis-pricing is lower for firms receiving greater coverage of their earnings announcements. Blankespoor et al. (2018) provides evidence that algorithmic articles of firms' earnings announcements produced by the Associated Press and disseminated by large media outlets lead to higher trading volume and liquidity.

2.2. Research hypotheses

2.2.1. Increased media coverage of earnings releases

Coverage of firms' earnings releases by media outlets is a function of the demand for such information, which can vary over time. As shown in Veldkamp (2006), because complementarity in information acquisition can arise, the media can maximize their profitability by obtaining information with a price that will exceed the cost of obtaining and disseminating the information.[7] The investment represents, for instance, the cost of a journalist preparing a story or obtaining non-public information. As the number of purchasers of the information increases, the cost is spread out, making the investment in information more profitable. The relative value of the information

[7] Whether the cost is fixed or variable only matters over the very short-run. Within Veldkamp (2006), the cost of a story is primarily fixed as news organizations are constrained in the short-run by their personnel, information, and time for collecting and synthesizing information and then disseminating news stories. Over longer periods virtually all costs are variable, as news organizations can shift almost all production costs. For instance, investments in individual journalists are variable costs. Consistent with this, 100,000 journalists have been fired over the last decade Thompson (2016), while over 10,000 new journalist majors graduate each year (see: https://datausa.io/profile/cip/090401/).

obtained will dictate the price that the individual supplier can charge and, accordingly, the expected cost it is willing to incur. The media generally incurs relatively low production costs to acquire information. This is in contrast to other more specialized suppliers of information that incur high production costs (e.g., investment advisors with private newsletters).

Higher demand for media coverage is expected to arise when uncertainty about asset payoffs grows. Veldkamp (2006) demonstrates that important shifts in the aggregate demand for information can occur when common shocks occur to the variance of firms' expected future payoffs, as the shocks to expected payoffs are multiplicative and time-varying. Because news stories become more valuable during such times due to the higher variance of expected payoffs, there should be an outward shift in demand for news stories.[8] Although less formal than Veldkamp (2006), Jensen (1979) also predicts that consumer preferences—especially aversion to ambiguity—shape the demand for news. In addition, this prediction is consistent with prior findings that investors dislike uncertainty, requiring a premium for holding assets with high uncertainty risk (e.g., Bansal and Yaron, 2004; Drechsler, 2013; Kumar, 2009; Ozoguz, 2009; Segal et al., 2015).

Because of the greater demand, periods of higher market uncertainty can lead to significant increases in media coverage. This prediction is premised on the media paying attention to changes in market uncertainty. Consistent with this assumption, as Baker et al. (2016) shows, the top 10 leading U.S. newspapers increase their coverage of major events that create economic policy uncertainty, as measured by their text-based economic policy uncertainty (EPU) index. Also, using an alternative text-based uncertainty measure from front-page articles of the *Wall Street Journal*, Manela and Moreira (2017) shows that the media closely tracks their coverage with information also contained in the VIX.

To gain further insight, we interviewed senior journalists that have written for major business press outlets including *Bloomberg News*, *Dow Jones Newswires*, *Forbes*, *The Financial Times*, *The New York Times*, and *The Wall Street Journal*. Consistent with our assumption, journalists indicated that the business press actively monitors investor demand for information. For instance, one

[8] The increased demand can come from readers that follow the firm about which the story is written and readers who are trying to learn about macroeconomic uncertainty through multiple noisy signals from a wide number of firms; the latter can occur as individual firm's earnings reveal important information about the macroeconomy (Anilowski et al., 2007; Bonsall et al., 2013; Aobdia et al., 2014).

journalist indicated that "stories get pushed based on what investors are searching for. Our analytics allows us to see what people are looking for and we respond to what the readers are requesting, [based on such inputs as] Google searches, other newspapers, and social media." Our interviews of journalists also included questions about how and why the media shift coverage during periods of market uncertainty (e.g., what types of news stories are more common during periods of greater uncertainty). We discuss the relevant institutional insights gained through our interviews in later sections of the study.

While the media could increase all types of coverage in response to heightened demand for information, we predict that the media will increase their coverage of earnings releases rather than all possible types of news stories. The media face short-term supply constraints that force them to make trade-offs in their coverage decisions. Increasing the supply of stories, particularly original stories, requires costly investments in hiring and training journalists, and in acquiring private information.[9] In addition, the information that firms and other information intermediaries provide may be affected by higher uncertainty; accordingly, the cost of acquiring some types of information may also increase with market uncertainty. Because of these constraints and the media's role as a low-cost information supplier, we predict that the media will shift toward news stories that are relatively low cost, predictable, and relevant. Firms' earnings announcements possess all three attributes. Specifically, the gathering and dissemination of earnings information is relatively inexpensive and firms' announcement dates can be readily anticipated. In addition, as shown in prior research, the media's dissemination of earnings information has important capital market consequences.

Whether the media respond to greater demand for coverage by increasing their capacity to supply coverage or by altering the mix of coverage they provide, however, depends on the net benefit to the media. Despite the increased demand for coverage during periods of higher uncertainty, the needed outlay of expenditures to increase the resources to acquire, process, interpret, and disseminate earnings information could preclude significant coverage changes by the media. Additionally,

[9] The notion that the press is constrained in its provision of news stories is pervasive in practice. Randall (2000) describes the constraints in this way: "There are limits to the process of journalism. Shortage of time and information are two which are endemic." Our interviews with senior journalists indicated that short-term constraints continue today, even in the digital news environment. For instance, one journalist indicated, "all newsrooms are stressed based on the number of people available for coverage."

unlike the demand for greater coverage of specific types of firms (e.g., larger firms), temporary demand shifts brought about by higher market uncertainty can be relatively unpredictable.

2.2.2. Capital market consequences of increased coverage of earnings releases

When the level of market uncertainty increases, greater demand for coverage of earnings information can lead to the media having a more important role as an information intermediary. If the media shift resources to increase the dissemination and interpretation of earnings information, a greater number of traders will receive the information and update their beliefs. This can lead to important changes in prices, trading volume, and price efficiency. First, following Holthausen and Verrecchia (1990), larger abnormal price changes will occur if the increased dissemination and interpretation of earnings announcements leads to greater informedness (i.e., the degree to which investors become more informed) and consensus (i.e., the degree of agreement among investors). In addition, larger abnormal trading volume will occur if the increased coverage leads to greater informedness; however, lower (higher) abnormal volume will be observed if the increased coverage leads to greater (lower) consensus. Thus, unlike abnormal price changes, whether higher or lower abnormal trading volume will occur depends on whether lower consensus complements greater informedness or whether greater consensus dominates. Accordingly, the two types of market reactions to earnings announcements can provide different insights into investors' reactions when media coverage grows during periods of higher market uncertainty.

Second, greater media coverage of earnings announcements during such times can lead to trading and pricing being more or less efficient. On one hand, the increased coverage could overcome investor limited attention issues when uncertainty is higher, resulting in improved price efficiency. Prior research suggests that investors face limited attention with regard to firm-specific information (e.g., Bloomfield, 2002; Hirshleifer et al., 2009; Hirshleifer and Teoh, 2003; Merton, 1987; Peng and Xiong, 2006). The media, in their role as an information intermediary, can both disseminate and synthesize the information released in earnings announcements, lowering information acquisition and interpretation costs and improving price efficiency (e.g., Bushee et al., 2010; Fang and Peress, 2009; Tetlock, 2010). Empirical evidence indicates that the media can serve such a role, finding that media coverage reduces mispricing (Drake et al., 2014), information asymmetry (e.g., Blankespoor et al., 2018; Soltes, 2011) and the cost of capital (e.g., Fang and Peress, 2009; Kothari et al., 2009).

These findings are consistent with the gradual diffusion of news model of Hong and Stein (1999).

On the other hand, greater coverage could lead to more attention-driven trading at the worst possible time (i.e., higher market uncertainty), resulting in diminished price efficiency. Chan (2003) and Vega (2006) find that price drift is greater for news receiving coverage by the media. Barber and Odean (2008) provides evidence that coverage leads individual investors to purchase stocks receiving attention. Engelberg et al. (2012) offers evidence that stock recommendations from the popular television show *Mad Money* generate attention-based trading and overnight returns that subsequently reverse in later months. Bushee et al. (2018) finds that such attention-driven trading is more pronounced during IPO quiet periods. In addition, Tetlock (2011) shows that individual investors trade on stale news stories and that such trading leads to subsequent price reversals. Further, some case studies provide evidence of large price and volume changes to media coverage that simply rebroadcast news made public months earlier (e.g., Huberman and Regev, 2001). Finally, during heightened market uncertainty, media coverage can have a more pronounced effect on short-term price distortions due to greater investor sensitivity to news (e.g., Garcia, 2013; Williams, 2014). Because of these differing possibilities, we do not make a directional predication regarding how greater media coverage of earnings announcements during periods of higher market uncertainty affects trading and price efficiency.

3. Research design

3.1. Increased media coverage of earnings releases

Our first set of empirical tests examines how market uncertainty leads to systematic increases in media coverage of earnings announcements. We begin by investigating whether media coverage of earnings announcements grows with market uncertainty using the following OLS regression model:

$$LCoverage_X = \alpha_0 + \alpha_1 VIX + \sum \alpha_i Control_i + \epsilon \qquad (1)$$

where $LCoverage_{EA}$ is the natural logarithm of one plus the number of news articles with relevance scores greater than or equal to 90 captured by RavenPack on days $[0, +1]$ relative to the quarterly earnings announcement ($X = EA$); and VIX is the average level of the Chicago Board Options

Exchange Volatility Index during the period from five days following the announcement of quarter $t-1$ earnings to five days prior to the announcement of quarter t earnings.

We test whether significant increases in media coverage during times of higher market uncertainty are concentrated at earnings announcements or are, alternatively, attributable to increased demand for all types of information. Our approach, similar to that adopted by Bushee et al. (2010), uses non-earnings announcement periods as a benchmark to evaluate the effect of market uncertainty on the coverage of earnings announcements relative to the coverage of other news. Our approach differs from that of Bushee et al. (2010) as we estimate separate models for the earnings announcement and non-earnings announcement periods, rather than one model for abnormal earnings announcement coverage. The dependent variable for the non-earnings announcement periods, $LCoverage_{NonEA}$, is the natural logarithm of one plus the number of stories written about firm i on non-earnings announcement trading days ($X = NonEA$) that fall between the current and most recent prior earnings announcement divided by the number of non-overlapping two-day non-earnings announcement trading days (for comparability with $LCoverage_{EA}$).[10] We expect that α_1 when $LCoverage_{EA}$ is the dependent variable will be greater than when $LCoverage_{NonEA}$ is the dependent variable.

We also examine how other market participants alter their actions in response to higher market uncertainty and how the media coverage is influenced by their actions. First, we investigate how firms change their disclosure practices in response to higher market uncertainty. Such change can occur if investors demand greater disclosure during more uncertain times. Managers may respond to the heightened demand by increasing their disclosures. Alternatively, managers may decrease their disclosure due to the increased uncertainty. Consistent with managers facing greater costs or limitations of disclosing forward-looking information, Kim et al. (2015) find that managers are less likely to issue management earnings forecasts during periods of elevated macroeconomic uncertainty.[11] Second, we investigate how analysts change their forecasting behavior in response to

[10] Our approach is equivalent to Bushee et al. (2010) except that it allows for the estimation of separate coefficients in the earnings and non-earnings announcement periods. Specifically, Bushee et al. (2010) measure abnormal press coverage as: $ABN\_PRESS = Ln\left((1 + PRESS_{EVENT}) / (1 + PRESS_{PRE})\right)$. Accordingly, by the quotient rule, coefficient estimates when using ABN_PRESS equal those from the separate estimation of $Ln\left(1 + PRESS_{EVENT}\right)$ minus those from the separate estimation of $Ln\left(1 + PRESS_{PRE}\right)$.

[11] Nagar et al. (2019) find, however, that managers are more likely issue forecasts when economic policy uncertainty is higher.

higher uncertainty. Loh and Stultz (2017) find that during periods of macroeconomic uncertainty analysts work harder by providing more accurate forecasts conditioned on the level of macroeconomic uncertainty and more frequent earnings forecasts. Loh and Stultz (2017) also find, however, that during such times there are significant reductions in analyst ranks, consistent with shrinking compensation and greater attrition. These changes in manager and analyst behavior during periods of higher market uncertainty could lead to changes in media coverage, as their disclosures and forecasts are common sources of information for journalists' stories (Call et al., 2018).

To examine how changing firm disclosure and analyst forecasting practices affect media coverage during periods of higher market uncertainty, we use a mediation model (i.e., path analysis) approach following the suggestions of MacKinnon and Dwyer (1993) and Hayes and Rockwood (2017). Prior accounting research has used path analysis to formally test whether a relationship between X and Y arises through path Z (e.g., Bonsall et al., 2018; Bonsall and Miller, 2017; Landsman et al., 2012; Lang et al., 2012). In our analysis, we decompose the total effect of the relationship between VIX and $LCoverage_X$ in equation (1) into the mediated paths resulting from changes in firm disclosure and analyst forecast revisions and the direct path of $VIX \rightarrow LCoverage_X$. Our mediator variable for firm disclosure is $LForm8K$, the natural logarithm of one plus the number (two-day averaged number) of Form 8-K filings by a firm during the earnings (non-earnings announcement) window. Form 8-Ks are collected from the SEC EDGAR database using an approach similar to Guest (2018). We use the release of Form 8-Ks as they typically relate to material events that arise in day-to-day changes in operations, performance, financial information, governance, and trading (e.g., Lerman and Livnat, 2010). Also, other forms of voluntary disclosure, such as management earnings forecasts and press releases, generally overlap with the release of a Form 8-K. For instance, Chuk et al. (2013) finds that the overlap of management forecasts in Form 8-Ks and press releases is 94 percent but that their inclusion is more common in Form 8-Ks. Our mediator variable for analyst forecasting activity is $LRevisions$, the natural logarithm of one plus the number (two-day averaged number) of analyst earnings forecast revisions made during the earnings (non-earnings announcement) window.

Certain types of firms are more likely to receive media attention than others do, such as large and growing firms. Our control variables are intended to capture the determinants of firms' normal level of media coverage. Specifically, similar to those used in prior related research (e.g., Blankespoor et al., 2018; Bonsall et al., 2018; Bushee et al., 2010; Drake et al., 2014, 2017; Fang and Peress, 2009;

Hillert et al., 2014) our control variables (defined in Appendix A) include $AbsEarnSurp$, $NegSurp$, $LMktCap$, $LFollow$, $InstHold$, $IVol$, Ret,[12] $SP500Member$, $LEmployee$, $LOwn$, $NasdaqTraded$, $Turnover$, and $MomStrength$. Despite our many controls, our causal interpretation of the findings could be threatened if other (unobservable) factors are correlated with our variable of interest, VIX, and $LCoverage_{EA}$. To mitigate this possibility, we conduct our tests using a firm fixed-effects model. This approach provides evidence of how the level of market uncertainty affects within-firm variation in media coverage.

3.2. Capital market consequences of increased coverage of earnings releases

3.2.1. Changing investor informativeness and consensus

Our next set of empirical tests examines the extent to which capital market outcomes during earnings announcements are negatively affected by higher market uncertainty and whether higher media coverage during such periods worsens or improves trading and pricing. We investigate these issues using the below model:

$$CapMktOutcome = \delta_0 + \delta_1 VIX + \sum \delta_i Control_i + \upsilon \qquad (2)$$

We first examine how investor informativeness and consensus change around earnings announcements. We investigate whether abnormal price changes at earnings announcements increase when market uncertainty is higher using $|AbnReturn|$, defined as the absolute value of the raw return minus the CRSP value-weighted index return during the earnings announcement period $[0, +1]$. Our measure of abnormal price changes follows Tetlock et al. (2008) and Tetlock (2011). As Tetlock et al. (2008) show, controlling for traditional risk factors has little effect on abnormal return calculations focused on short-window announcements of firm-specific news. Because the pre-disclosure precision of information should be lower when market uncertainty is higher and the release of earnings information should lead to greater belief revisions (Veldkamp, 2006), abnormal price changes should be higher when market uncertainty is higher.

[12] We control for firm-specific returns to alleviate concerns that good or bad news determines the level of media coverage. We do not directly control for market-level returns, however, as prior work by Romer (1990), Fernández-Villaverde et al. (2011), Fernández-Villaverde et al. (2015), and Barrero et al. (2017) demonstrates, changes in the business cycle are caused by shocks to macroeconomic uncertainty.

We also examine whether there is abnormal trading volume when market uncertainty is higher using $AbnVol$, defined as share turnover during the earnings announcement period $[0, +1]$ less the median two-day share turnover of consecutive two-day periods during the non-announcement period. The non-announcement period is comprised of all dates between five trading days subsequent to the release date of quarter $t-1$ earnings and five trading days prior to the release date of quarter t earnings. Our measure of abnormal volume is similar to that used in Barron et al. (2018). We expect that abnormal trading volume surrounding earnings announcements will be higher when market uncertainty is higher. This prediction assumes again that pre-disclosure precision of information is lower when market uncertainty is higher and that the release of earnings information leads to greater belief revisions. In models of trading volume (Kim and Verrecchia, 1991a,b), greater differential precision of information before earnings announcements can lead to greater revisions to investors' beliefs when earnings are released. Empirical studies examining earnings announcements support this prediction (e.g., Bamber et al., 2011). However, if the release of earnings during such times leads to greater investor consensus dominating greater informativeness, lower abnormal trading volume will be observed.

We directly investigate whether increased media coverage during periods of higher market uncertainty is responsible for the predicted changes in prices and trading volume in equations (2) and (3) using path analysis. Specifically, we decompose the total effect of the relationship between VIX and $|AbnReturn|$ and $AbnVol$ into mediated paths resulting from changes in media coverage, as well as changes in firm disclosure and analyst forecast revisions. Our mediator variables are $LCoverage_{EA}$, $LForm8K$, and $LRevisions$. For $|AbnReturn|$ and $AbnVol$, the combined indirect paths of $VIX \rightarrow LCoverage_{EA} \rightarrow |AbnReturn|$ and $VIX \rightarrow LCoverage_{EA} \rightarrow AbnVol$ are of primary interest. Control variables included in the analyses are the same as equation (1) and are consistent with those used in prior related research.

3.2.2. Changing price efficiency

Abnormal price changes and trading volume around earnings announcements could yield results that are caused by more information being available to investors through greater media coverage or by uninformed investors trading more in response to greater coverage. Accordingly, our last set of tests explores whether price efficiency improves or declines around earnings announcements.

Information asymmetry

Greater coverage by the media at earnings announcements can reduce information asymmetry (i.e., narrower bid-ask spreads and greater depth). Examining different samples of firms, Bushee et al. (2010), Soltes (2011), and Blankespoor et al. (2018) find supporting evidence of a reduction in information asymmetry. During periods of increased market uncertainty, greater coverage could also lead to improvements in information asymmetry (e.g., lower spreads and greater depth), have no effect given the increased market uncertainty, or even lead to greater information asymmetry as the increased market uncertainty could provide sophisticated investors with an information advantage at earnings announcements. We investigate how increased market uncertainty affects information asymmetry at earnings announcements using two variables for information asymmetry: *AbnSpread* is the weighted average effective bid-ask spread during the earnings announcement period $[0, +1]$ less the median two-day weighted average effective bid-ask spread of consecutive two-day periods during the non-announcement period and *AbnDepth* is the weighted average bid and offer depth during the earnings announcement period $[0, +1]$ less the median two-day weighted average bid and offer depth of consecutive two-day periods during the non-announcement period. Following Holden and Jacobsen (2014) and Blankespoor et al. (2018), weighted average amounts are based on the amount of time during each trading day that the spreads and depth are in force. Similar to our investor informativeness and consensus tests, we examine the mediated paths arising from changes in media coverage, as well as disclosure and analyst forecast revisions, for *AbnSpread*, *AbnDepth*, in this and later tests. We also use the same control variables.

Intraperiod price timeliness

Greater media coverage of earnings announcements can also increase the speed by which earnings information is impounded into prices. Along these lines, Twedt (2015) finds that greater media dissemination of the release of management earnings forecast leads to greater efficiency in the incorporation of the information into price. Blankespoor et al. (2018), however, do not find that greater dissemination of automated articles by the Associated Press of earnings releases leads to greater speed of price discovery. During periods of higher market uncertainty, how greater media coverage affects price discovery is again unclear as the greater interpretation and dissemination of earnings information could speed price discovery, or alternatively, it could lead to biased or uninformed trading, particularly by retail investors. Our investigation of this possibility begins with examining how higher market uncertainty affects intraperiod price timeliness using IPT, defined as the adjusted intraperiod timeliness measure measured over the six-day earnings announcement window suggested by Blankespoor et al. (2018).[13] Larger IPT values are consistent with faster price discovery.

Trade by retail and non-retail investors

The greater attention and dissemination brought about by greater media coverage at earnings announcements can lead to more trade by retail investors. Consistent with such a possibility, Blankespoor et al. (2018) finds more retail trading volume following greater dissemination of automated articles by the Associated Press. When market uncertainty is higher, greater coverage could lead to more or less trade by retail investors. Such time periods could make retail investors more reluctant to trade due to the greater uncertainty, despite greater dissemination. Alternatively, it could make retail investors more likely to trade given heightened investor sensitivity and greater media dissemination of earnings information. In addition, the greater media coverage can lead to more trade by institutional investors, as the greater coverage increases the informedness of institutional investors. Accordingly, the actions of institutional investors provide greater insight into whether abnormal trading volume increases are attributable to increased investor informedness. The possibility exists that greater coverage at earnings announcement can lead to greater investor consensus, however, resulting in abnormally lower trading.

We examine these possibilities using two variables for abnormal trading: $AbnRetailVol$ is share turnover by retail investors during the earnings announcement period $[0, +1]$ less the median two-day share turnover by retail investors of consecutive two-day periods during the non-announcement period, which is comprised of all dates between five trading days subsequent to the release date of quarter $t-1$ earnings and five trading days prior to the release date of quarter t earnings and $AbnNonRetailVol$ is share turnover by non-retail investors during the earnings announcement

[13] As the internet appendix of Blankespoor et al. (2018) details, the original IPT measure of Butler et al. (2007) assumes that no return overreaction and reversal occurs during the five-day measurement window; the adjusted measure corrects for this possibility. Potential alternative measures of the efficiency of price responses to earnings information include cross-sectional differences in earnings response coefficients and longer-term post earnings announcement drift. Consistent with prior research examining the price effects of the media (e.g., Blankespoor et al., 2018), we focus on intraperiod price timeliness as these alternative measures further require conditioning on the market's expectation of earnings surprises.

period $[0, +1]$ less the median two-day share turnover by non-retail investors of consecutive two-day periods during the non-announcement period. The non-announcement period is comprised of all dates between five trading days subsequent to the release date of quarter $t-1$ earnings and five trading days prior to the release date of quarter t earnings. Retail trades are identified and separated from non-retail trades using the approach created by Boehmer et al. (2017) and adopted in recent related research (e.g., Bushee et al., 2018; Guest, 2018; Israeli et al., 2017). Unlike prior studies' use of trade size to identify retail trades, the Boehmer et al. (2017) approach relies on retail trades being filled off-exchange in broker's inventory or through wholesalers (identified as FINRA Trade Reporting Facility Trades with exchange code "D" trades on TAQ with small price improvements).

4. Sample and empirical results

4.1. Data and sample description

We begin our sample construction by selecting the intersection of the CRSP database and all quarterly earnings announcements in Compustat during the 2004–2013 period, yielding 291,449 observations. The availability of control variables for our regression analyses reduces the sample further to 112,725 firm-quarter (earnings announcement) observations. Following von Beschwitz et al. (2017), we collect news stories from the Dow Jones edition of the RavenPack 3.0 news database with news stories beginning in January 2004 and ending in December 2013.[14] During our sample period, the RavenPack database covers approximately 8,000 companies and tracks nearly 10 million unique news stories. For each story, RavenPack records a score, called Relevance, to indicate the prominence of a firm within the story with higher values corresponding to the greater prominence of a firm within the story. We count news stories each day as the number of news flashes or full (i.e., original) articles with a relevance score of at least 90 from the Dow Jones news service. As discussed by Drake et al. (2014), RavenPack's relevance score leads to the isolation of articles that focus on the companies in our sample. In addition, RavenPack's identification of articles as news

[14] Our sample period ending in 2013 avoids the dramatic increase in robo-journalism started by the Associated Press in 2014 (Blankespoor et al., 2018). However, other automated news flashes occur during our sample period to some extent at earnings releases (e.g., Dow Jones Newswire on February 12, 2013, "Clearwire Corp 4Q Loss/Shr 29c"). This would affect our tests if earnings announcement and non-earnings announcement news flashes are automated in systematic ways that occur in tandem with changes in market uncertainty.

flashes or full articles allows us to examine the possible asymmetric supply of news flashes relative to full articles. News stories that relate to stock prices or trade imbalances are dropped because a large number of these stories are automatically generated, and stories that relate to insider trading are dropped because of changes in their coverage during the sample period (Rogers et al., 2016). We winsorize all continuous variables in our sample at the 1st and 99th percentile sample values.

Table 1 presents descriptive statistics for variables used in our earnings announcement analyses and for the coverage variables used in our non-earnings announcement period analyses. During the two-day window starting on the earnings announcement date, there are, on average, 11 news articles. Of these articles, approximately 5.6 are news flashes and 2.3 are original news stories. The average news flashes and original news stories do not sum to the average total articles because RavenPack also includes press releases and tabular material (e.g., a firm's income statement) in its news coverage. Media coverage is dramatically lower, on average, during non-earnings announcement periods. This pattern exists for total coverage (average of 0.7 stories), news flashes (average of 0.3 stories), and original articles (average of 0.2 stories). This indicates that the nature of the demand for and supply of information at earnings announcements differs from other days during the fiscal quarter. The panel presents descriptive statistics for the other variables used in our analyses.

4.2. Increased media coverage of earnings releases

4.2.1. Primary results

Our first set of empirical results relates to whether media coverage of earnings announcements increases during periods of higher uncertainty. Panel A of Table 2 presents the formal path analysis for our mediation tests using equation (1) for earnings announcement and non-earnings announcement periods. We find that the direct path $VIX \rightarrow LCoverage_{EA}$ is significantly positive in column (1). This indicates that media coverage of earnings announcements grows with market uncertainty. In contrast, the direct path $VIX \rightarrow LCoverage_{NonEA}$ is significantly negative in column (2). The reduction in coverage during non-earnings announcement periods could be the result of constraints faced by the media. For instance, the increase in coverage of earnings announcements could limit the media's ability to cover non-earnings announcement events; a possibility we explore later. Also, the coefficient estimate for VIX during earnings announcements is significantly greater than the estimate during non-earnings announcement periods, as shown in column (3). The coefficient for abnormal media coverage at earnings announcements in column (3) of 0.0038 indicates that during an average earnings announcement a moderate increase in VIX from the first to third quartile leads to a 6.12 percent increase in the average number of stories).[15] For a more extreme change in market uncertainty, the effect is considerably higher. A large change in VIX from the bottom decile (12.225) to the top decile (30.929) leads to the average number of abnormal stories during earnings announcements increasing by 11.83 percent.

Regarding how market uncertainty affects firm-initiated disclosure and analyst revisions, during earnings announcements the indirect path for $LForm8K$ (i.e., the path $VIX \rightarrow LForm8K$ multiplied by $LForm8K \rightarrow LCoverage_X$) and $LRevisions$ is insignificant.[16] During non-earnings announcement periods, however, the indirect paths for $LForm8K$ and $LRevisions$ are significantly negative and positive, respectively. The coefficient differences for $LForm8K$ and $LRevisions$ presented in column (3) indicate that the abnormal indirect paths are significantly positive and negative, respectively. The differences in behavior during and outside earnings announcement periods likely reflect variation in the demand for information and the constraints faced by managers and analysts in providing information and updating their forecasts. Overall, however, the differences in these indirect paths largely offset, leading to the direct path of $VIX \rightarrow LCoverage_X$ being similar in magnitude as the total effect (e.g., 0.0067 relative to 0.0079 in column (3)). As shown in the last two rows of Panel A, the direct path for $VIX \rightarrow LCoverage_{EA}$ leads to a significantly larger increase in media coverage than the indirect paths for $LForm8K$ and $LRevisions$ during earnings announcements, and the direct path $VIX \rightarrow LCoverage_{NonEA}$ leads to a significantly larger decrease in media coverage than the indirect path for $LRevisions$ outside of earnings announcement periods.

Panel B reports the underlying mediated regression results. As expected, the coefficient estimates for the variables of interest are the same as the direct effects reported in Panel A. For the control variables, we find that media coverage of earnings announcements is significantly higher for firms with greater analyst following ($LFollow$), greater institutional holdings ($InstHold$), higher

[15]That is, $\{e^{[0.0030\times(24.784-15.009)]}-1\}\times\left[\frac{1+10.989}{10.989}\right]-\{e^{[-0.0008\times(24.784-15.009)]}-1\}\times\left[\frac{1+0.651}{0.651}\right]$. The calculation adjusts for $LCoverage_{EA}$ being constructed as the natural logarithm of one plus the number of news stories.

[16]In later analyses, with some exceptions, we only report the indirect paths for brevity rather than each coefficient estimate along each path. The full results are provided in the internet appendix.

returns (Ret), membership in the S&P 500 ($SP500Member$), more employees ($LEmployee$), more dispersed ownership ($LOwn$), and more turnover ($Turnover$). In addition, we find that coverage is significantly lower for firms with higher market capitalization ($LMktCap$), lower growth (BM), greater idiosyncratic volatility ($IVol$), and listed on NASDAQ ($NasdaqTraded$).[17] This evidence is consistent with demand by shareholders, employees, and others determining media coverage of earnings announcements. Similar results are found for non-earnings announcement coverage; however, we find that greater coverage for firms with higher market capitalization ($LMktCap$), greater idiosyncratic volatility ($IVol$), and lower returns (Ret). These differences across the earnings and non-earnings periods likely reflect differential demands and supply for coverage of earnings and non-earnings information—e.g., institutional investors could have greater demand for the dissemination of earnings information versus non-earnings information.

Next, we turn to more detailed analyses to provide greater insight into how and why the media make earnings announcement coverage decisions. We first examine the role of the level of market uncertainty and specific sources of uncertainty on such decisions. We next explore if greater coverage of earnings announcements during periods of higher market uncertainty "crowds out" the coverage of non-earnings news of other firms. We then investigate whether the media focus on certain types of news stories and firms when market uncertainty grows.

4.2.2. What levels of the VIX and types of uncertainty underlying the VIX are most important?

An interesting issue is at what levels of market uncertainty the media shift coverage of earnings announcements. For instance, the highest levels of the VIX, particularly during the 2007–2009 financial crisis, could be responsible for our findings given the extreme levels of market uncertainty. To explore this issue in greater detail, we estimate a piecewise regression for quartiles of the VIX. We drop VIX from equation (1) and include four VIX variables, VIX^{Q1}, VIX^{Q2}, VIX^{Q3}, and VIX^{Q4}, for each quartile of the VIX.[18] In Panel A of Table 3, we find that higher uncertainty within each quartile of the VIX leads to greater abnormal media coverage of earnings announcements, as shown in column (3). For instance, in the lowest quartile, we find direct paths

[17]The finding of lower coverage for firms with greater idiosyncratic volatility is consistent with the evidence in Soltes (2011) of market benefits for firms with greater media coverage.

[18]For brevity, we only report the direct paths for this analysis and those that follow. The full set of results for each analysis are reported in the online appendix.

(e.g., $VIX^{Q1} \rightarrow LCoverage_X$) for VIX^{Q1} during earnings announcements of 0.101 and during non-earnings announcement periods of -0.0016. The abnormal media coverage direct paths for the second, third, and fourth quartiles are similar: 0.0088, 0.0078, and 0.0086, respectively. These abnormal coverage sensitivities are over twice as high as those in our primary analysis in reported in Table 2, demonstrating the importance of allowing for differing levels of the VIX. Together, this evidence indicates that the media shift earnings announcement coverage across different levels of the VIX, not just for the highest levels.

Another interesting issue is what specific types of uncertainty underlying the VIX lead to greater media coverage. For instance, greater political-related events could lead to reductions in business press coverage, due to resources being diverted away to such issues, or an expansion in business press coverage, as market participants' demand for financial information increases. As prior research (e.g., Alfaro et al., 2018; Barrero et al., 2017; Stein and Wang, 2016) finds, shocks to aggregate market uncertainty are caused by economic policy uncertainty (e.g., debates over the U.S. debt ceiling, participation in wars overseas, and fiscal policy), variation in the price of oil, and exchange rates.

Figure 1 shows how the three sources of uncertainty vary with the VIX over time. The first index, EPU, captures economic policy uncertainty.[19] The second index, oil price uncertainty or the oil price volatility index, is the closing price of the CBOE crude oil ETF volatility index. The third index, exchange rate uncertainty or the currency volatility index, is the mean volatility index of the following volatility indices: CBOE FX Euro Volatility index, FX Yen Volatility Index, FX British Pound Volatility Index, and the EuroCurrency Volatility Index. To facilitate comparisons, each index uses month-end values and each series is transformed to a standard normal distribution. As the figure shows, the different sources of uncertainty are related but have some differences. For instance, similar to Baker et al. (2016), the EPU index is dramatically higher during tight presidential elections, Gulf Wars I and II, the 9/11 attacks, the failure of Lehman Brothers, the 2011 debt ceiling dispute, and other major battles over fiscal policy.[20] In contrast, the oil price

[19] Baker et al. (2016) measures this as the relative frequency of the trio of terms "uncertainty" or "uncertain"; "economic" or "economy"; and one of the following policy terms: "Congress," "deficit," "Federal Reserve," "legislation," "regulation," or "White House" (including variants like "uncertainties," "regulatory," or "the Fed" in the top 10 leading newspapers in the United States. We appreciate the public posting of the EPU index by Scott Baker, Nick Bloom, and Steven Davis and the data from Barrero et al. (2017).

[20] Nagar et al. (2019) provide evidence that changes in economic policy uncertainty are important for individual

volatility index rises dramatically in 2007 during a rapid oil price increase while other indices are unaffected. In addition, economic policy uncertainty decreases after Obama's reelection without a similar decrease in other indices. The spikes in uncertainty common to most of the indices are during the global banking crisis, the European debt crisis, and the U.S. debate on the debt ceiling.

We investigate how these underlying sources of aggregate market uncertainty, as well as unexplained variation in the VIX, individually contribute to abnormal media coverage. Variables for each of the three indexes are denoted as EPU, $OilVol$, and $CurrVol$. To directly examine how each influences the VIX, we first regress each variable on VIX using monthly observations. As shown in Appendix B, all three variables are significantly positive and jointly explain 89.7 percent of the variation in VIX. We then investigate the role of each by using the predicted value of each, denoted as VIX^{EPU}, VIX^{OilVol}, and $VIX^{CurrVol}$, respectively, rather than VIX in equation (1). The residual from the first-stage regression is also included as a measure of other sources of uncertainty, denoted as VIX^{Other}, that affect the VIX. To ease comparability, all variables are standardized. In Panel B of Table 3, we find that VIX^{EPU}, $VIX^{CurrVol}$, and VIX^{Other} lead to greater abnormal media coverage of earnings announcements. As indicated by the significant z-tests in the last rows of Panel B, VIX^{EPU} is relatively more important for changes in earnings announcement coverage than VIX^{OilVol}, $VIX^{CurrVol}$, and VIX^{Other}. This suggests that the media make the greatest changes when economic policy uncertainty shocks occur.

4.2.3. Does increased earnings announcement coverage crowd out non-earnings announcement coverage?

Our primary findings suggest that media coverage of non-earnings announcement stories falls with market uncertainty. Consistent with the views of the senior journalists whom we interviewed, one possibility for this decline is that the increased earnings announcement coverage for other firms crowds out the coverage of firms' non-earnings announcement news. We test this possibility by further mediating equation (1) for non-earnings announcement coverage by including $LCoverage_{EA,Other}$, the amount of other firms' earnings announcement coverage during the same two-day window, as a mediator variable. The results of this analysis are presented in Table 4. As shown, the indirect path of VIX $\rightarrow$ $\mathrm{LCoverage}_{\mathrm{EA,Other}}$ is significantly positive, consistent with

firms, leading to higher bid-ask spreads and lower responses to earnings releases.

our earlier findings that higher market uncertainty leads to greater coverage of earnings announcements. In addition, the indirect path of $\text{LCoverage}_{\text{EA,Other}} \rightarrow \text{LCoverage}_{\text{NonEA}}$ is significantly negative, consistent with the coverage of other firms' earnings announcements leading to reduced coverage of firms' non-earnings announcement news. Combined, the indirect effect attributable to $LCoverage_{EA,Other}$ is significantly negative, providing evidence that non-earnings announcement coverage is crowded out by the increased coverage of other firms' earnings announcements during periods of higher market uncertainty. In the last row of Table 4, we also provide evidence that the reduction in coverage from the indirect effect attributable to $LCoverage_{EA,Other}$ is statistically different from the increase in coverage brought about by the increased frequency in analyst revisions outside of earnings announcement periods.

4.2.4. Does the media shift to specific types of news stories and firms?

Active monitoring of user demand for information can lead the media to shift their coverage toward certain types of news stories and firms and away from others during periods of increased market uncertainty. Consistent with such shifts taking place, our interviews of journalists indicated that greater inferred demand during such times can lead to greater dissemination of earnings information through quick and simple stories that re-iterate key metrics in earnings releases. In addition, during periods of greater uncertainty, journalists pointed out that there is more news and more opportunities to provide more information. Because of these changes, journalists suggested that a story can get split across multiple reporters rather than just one reporter and can lead to reporters sticking with a particular firm for a longer period of time. The shift in coverage can lead to a reduction in the number of by-lined stories, especially enterprise stories (e.g., investigations about wrongdoing), as newsrooms are stressed by the number of journalists available for coverage. Together, this anecdotal evidence suggests that during times of higher uncertainty the media could move to increase the number of news flashes relative to the number of original stories, which could decrease.[21]

We formally investigate whether the media make such shifts in news stories by examining coverage decisions separately for news flashes, $LCoverage_{X,Flash}$, and original articles, $LCoverage_{X,Orig}$.

[21] As Drake et al. (2014) shows, news flash stories typically only rebroadcast a disclosure and are relatively short articles, containing on average 42 words. In contrast, full article stories can rebroadcast a disclosure but also include reporter-generated information and are much more extensive stories, containing on average 248 words.

$LCoverage_{X,Flash}$, is the natural logarithm of one plus the number of news flashes for a firm on the day of or the day after a quarterly earnings announcement ($X = EA$) or during the two-day averaged non-earnings announcement period ($X = NonEA$). $LCoverage_{X,Orig}$, is the natural logarithm of one plus the number of original news stories for a firm on the day of or the day after a quarterly earnings announcement ($X = EA$) or during the two-day averaged non-earnings announcement period ($X = NonEA$).The test of our prediction is that the coefficient for $LCoverage_{EA,Flash}$ is greater than that for $LCoverage_{EA,Orig}$. The formal test for the difference in coefficients is conducted by stacking the separate equations.

Panels A and B of Table 5 provide the results for $LCoverage_{EA,Flash}$ and $LCoverage_{EA,Orig}$ as dependent variables, respectively. The results indicate that news flash coverage is more sensitive to increases in market uncertainty than original articles. For news flash stories during earnings announcements, the direct path estimate for VIX of 0.0067 is significantly positive. For original articles during earnings announcements, the direct path estimate of -0.0075 is significantly negative. In untabulated tests, the difference in the VIX coefficients of 0.0142 for the two types of stories is significantly positive. For news flashes, during non-earnings announcement trading days, we find that the direct path estimate for VIX is insignificant. In addition, we find that the positive coefficient for VIX during earnings announcement periods is significantly greater than that during non-earnings announcement periods; the difference of 0.0063 is much larger than the difference of 0.0038 observed for our primary analysis, which combines news flashes with original articles. This evidence indicates that news-flash coverage during earnings announcements grows with market uncertainty but is relatively unaffected outside of earnings announcements. For original articles, during non-earnings announcement periods, the direct path estimate for VIX is significantly negative and, in untabulated tests, is statistically more negative than the estimate during earnings announcement periods. The last two rows in Panels A and B indicate that the changes in coverage from the direct paths of $VIX \rightarrow LCoverage_{EA}$ and $VIX \rightarrow LCoverage_{NonEA}$, as well as the differences in estimates, are significantly greater (in absolute value) than the indirect paths for $LForm8K$ and $LRevisions$, with the exception of $VIX \rightarrow LCoverage_{NonEA}$ not being significantly greater than the indirect path for $LRevisions$.

User demand for earnings information can also increase or decrease for certain types of firms during periods of higher market uncertainty. First, we expect greater demand for earnings information of bellwether firms relative to non-bellwether firms. As Anilowski et al. (2007), Aobdia et al. (2014), and Bonsall et al. (2013) observe, bellwether firms' disclosures can be a source of important information about macroeconomic activity, as evidenced by significant aggregate stock market responses to the release bellwether firms' management earnings forecasts. By focusing on the news regarding bellwether firms, the media can provide answers to investors regarding a bellwether firm's uncertainty but, more importantly, provide information to investors about macroeconomic uncertainty in general. Second, we expect greater demand for earnings information of early announcing firms in a quarter relative to late announcing firms. As Savor and Wilson (2016) finds, the earnings announcements of early announcing firms provide greater information about aggregate earnings in a given period; this result is intuitive as less information is known earlier in the quarter. Our interviews of journalists suggest that changes in demand for those types of firms can occur during periods of higher market uncertainty.

We separately examine whether the expansion of coverage during earnings announcements is more pronounced for bellwether and early announcing firms by including interactions of VIX with $Bellwether$ and $EarlyAnnouncer$. $Bellwether$ is an indicator variable with a value of one if the explanatory power of various macroeconomic indices for a firm's earnings is in the upper quartile of the sample distribution (Bonsall et al., 2013), and zero otherwise. $EarlyAnnouncer$ is an indicator variable with a value one if a firm's expected earnings announcement date is in the earliest quartile in a given fiscal quarter (Savor and Wilson, 2016), and zero otherwise. In addition, we explore whether firms whose earnings are less informative about aggregate uncertainty lose coverage or have less of an increase in coverage during times of higher uncertainty. We investigate this possibility by including interactions of VIX with $Non-Bellwether$ and $LateAnnouncer$. $Non-Bellwether$ is an indicator variable with a value of one if the explanatory power of various macroeconomic indices for a firm's earnings is in the lower quartile of the sample distribution (Bonsall et al., 2013), and zero otherwise. $LateAnnouncer$ is an indicator variable with a value one if a firm's expected earnings announcement date is in the latest quartile in a given fiscal quarter Savor and Wilson (2016), and zero otherwise. We expect a positive coefficient on the interaction of VIX with $Bellwether$ and VIX with $EarlyAnnouncer$, and a negative coefficient on the interaction of VIX with $Non-Bellwether$ and VIX with $LateAnnouncer$.

Panels C and D of Table 5 present the moderated path analysis findings for bellwether versus non-bellwether firms and early versus late announcing firms, respectively. Only the direct paths are reported for parsimony; the detailed mediated paths are reported in the online appendix. In Panel C, for bellwether firms, the interaction $VIX \times Bellwether$ is significantly positive for abnormal earnings announcement coverage. The estimate of the of 0.0041 indicates that the coverage of bellwether firms at earnings announcements is much more sensitive to market uncertainty. An interquartile-range increase in the VIX leads to a 22.09 percent increase in the average number of stories for bellwether firms. For non-bellwether firms, the interaction $VIX \times Non - Bellwether$ is significantly negative. The estimate of -0.0064, when considered together with the estimate for other firms of 0.0041, indicates that the coverage of non-bellwether firms is relatively insensitive to market uncertainty. An interquartile-range increase in the VIX leads to a 0.04 percent increase in the average number of stories for non-bellwether firms. In Panel D, we fail to find that the interaction $VIX \times EarlyAnnouncer$ for abnormal earnings announcement coverage is significant. For late announcing firms, however, we find that the interaction $VIX \times LateAnnouncer$ is significantly negative. The estimate of -0.0004 suggests only a modest lower sensitivity to market uncertainty. Together, this evidence is consistent with the media responding to changing demand for earnings information during periods of increased market uncertainty by increasing their coverage of bellwether firms and increasing their coverage less for non-bellwether and late announcing firms.

4.3. Capital market consequences of increased coverage of earnings releases

Having established that the supply of media stories during earnings announcements increases when there is higher market uncertainty, we next turn to how the change in coverage affects capital markets. We use path analyses to directly test whether the increased supply leads to changes in investor consensus and informedness and price efficiency.

4.3.1. Changing investor consensus and informativeness

Table 6 presents the results from estimating the mediated analyses for abnormal price changes, $|AbnReturn|$, and abnormal stock return volatility, $AbnVol$, using bootstrapped standard errors clustered by firm and year-quarter (MacKinnon et al., 2004). In column (1), the significantly positive indirect path $VIX \rightarrow LCoverage_{EA} \rightarrow |AbnReturn|$ indicates that greater media coverage associated with higher uncertainty leads to greater abnormal return volatility. The coefficient estimate of 0.000279 implies that an increase in VIX from its first to third quartile value leads to a 5.8 percent ($0.000279 \times (24.784 - 15.009) \div 0.047$) increase in abnormal volatility at earnings announcements through increased media coverage relative to the mean level in our sample. We also find that the indirect path of $VIX \rightarrow LForm8K \rightarrow |AbnReturn|$ is insignificant but find evidence that the indirect path of $VIX \rightarrow LRevisions \rightarrow |AbnReturn|$ is statistically negative, suggesting that higher market uncertainty leads to fewer analyst revisions and, in turn, lower abnormal return volatility. As shown in the last two rows of the table, we find that the indirect path for $LCoverage_{EA}$ is significantly greater than the indirect paths for $LForm8K$ and $LRevisions$. This evidence suggests that coverage by the media has relatively greater influence on abnormal return volatility during periods of higher market uncertainty than firm-initiated disclosures and analyst forecast revisions. The significantly positive direct path from VIX to $|AbnReturn|$ indicates that abnormal stock return volatility is higher during periods of higher market uncertainty after taking into account the media, firm-initiated disclosure, and analyst forecast revisions.

In column (2), we find similar evidence for abnormal trading volume. The indirect path of $VIX \rightarrow LCoverage_{EA} \rightarrow AbnVol$ is significantly positive. The coefficient estimate of 0.000170 indicates that an increase in VIX from its first to third quartile value leads to a 4.3 percent ($0.000170 \times (24.784 - 15.009) \div 0.039$) increase in abnormal volatility at earnings announcements through increased media coverage relative to the mean level in our sample. We also find that the indirect path of $VIX \rightarrow LForm8K \rightarrow AbnVol$ is insignificant, the indirect path of $VIX \rightarrow LRevisions \rightarrow AbnVol$ is significantly negative, and the direct path of $VIX \rightarrow AbnVol$ is significantly positive.

4.3.2. Changing price efficiency

The increased abnormal stock price volatility and trading volume suggest that the greater media coverage during periods of higher market uncertainty lead to greater investor informedness. In this sub-section, we go further and explore whether greater coverage leads to greater price efficiency.

Information asymmetry

Panel A of Table 7 provides the results of our formal path analysis for abnormal spreads and depth. We find that the indirect path estimates $VIX \rightarrow LCoverage_{EA} \rightarrow AbnSpread$ and $VIX \rightarrow LCoverage_{EA} \rightarrow AbnDepth$ are significantly negative and positive, respectively. This evidence suggests that greater coverage during periods of higher uncertainty leads to important improvements in information asymmetry. When compared to the positive and negative direct path estimates of $VIX \rightarrow AbnSpread$ and $VIX \rightarrow AbnDepth$, the findings suggest that media coverage helps mitigate increased information asymmetry brought about by increased market uncertainty. The coefficient estimates for the indirect paths for media coverage of -0.000762 and 0.00116 indicate that that an increase in VIX from its first to third quartile value leads to a 14.9 percent ($-0.000762 \times (24.784 - 15.009) \div 0.050$) decrease in abnormal spreads and a 75.6 percent ($0.00116 \times (24.784 - 15.009) \div 0.015$) increase in abnormal depth at earnings announcements through increased media coverage relative to the mean. We do not find that the indirect path estimates for firm disclosures and analyst forecast revisions lead to change in information asymmetry, with the exception of the significantly positive indirect path $VIX \rightarrow LRevisions \rightarrow AbnSpread$. This finding indicates that fewer analyst revisions at earnings announcements during periods of market uncertainty lead to higher abnormal spreads. The last two rows of Panel A show that the indirect path estimates for $LCoverage_{EA}$ have a statistically greater effect on abnormal spreads and depth than the indirect paths for $LForm8K$ and $LRevisions$.

Intraperiod price timeliness

Panel B presents the results of the path analysis for intraperiod price timeliness. The indirect path estimate for $VIX \rightarrow Coverage_{EA} \rightarrow IPT_{Adj}$ is significantly positive. This evidence indicates that greater media coverage due to higher market uncertainty increases intraperiod price timeliness. The coefficient estimate of 0.00339 implies an increase of 1.00 percent for an interquartile increase in the VIX. In contrast, the direct effect estimate of $VIX \rightarrow IPT_{Adj}$ is statistically negative. Accordingly, while periods of market uncertainty lead to slower intraperiod price timeliness at earnings announcements, firms with greater media coverage during such times face relatively faster price timeliness. In addition, the indirect path $VIX \rightarrow LRevisions \rightarrow IPT_{Adj}$ is significantly negative, indicating that fewer analyst revisions when market uncertainty is higher leads to slower intraperiod price timeliness at earnings announcements. The last two rows of Panel B indicate that the positive indirect path estimate for intraperiod price timeliness related to media coverage is significantly greater than the indirect path estimates related to firm-initiated disclosures and analyst forecast revisions.

Trade by retail and non-retail investors

Panel C gives the results of the path analyses for retail and non-retail trading volume. The indirect paths estimates for $VIX \rightarrow LCoverage_{EA} \rightarrow AbnRetailVol$ and $VIX \rightarrow LCoverage_{EA} \rightarrow AbnNonRetailVol$ are significantly positive. We also find that the direct path estimates $VIX \rightarrow AbnRetailVol$ and $VIX \rightarrow AbnNonRetailVol$ are significantly positive and negative, respectively. These findings suggest that—while greater market uncertainty leads to greater and lower abnormal volume by retail investors and non-retail investors—the greater media coverage of earnings releases during such times leads to greater abnormal volume by both types of traders. In contrast to this evidence for coverage by the media, we find that fewer analyst forecast revisions during such times leads to decreased volume by both retail and non-retail traders, as indicated by the significantly negative indirect path estimates. As shown in the last two rows, the positive indirect path estimates for $LCoverage_{EA}$ are significantly greater than the indirect paths for $LForm8K$ and $LRevisions$.

Together, the evidence suggests that greater media coverage when market uncertainty is higher mitigates greater information asymmetry and delayed intra-period price timeliness at earnings announcements, and leads to greater trade by both retail and institutional traders, which presumably are not subject to limited attention trading biases. With regard to other important providers of information during such times, we are unable to find evidence that firm-initiated disclosures improve the efficiency of capital markets and find evidence that less frequent analyst forecast revisions at earnings announcements leads to reduced price efficiency.

5. Conclusion

This study provides evidence of how the media serves an enhanced role as an information intermediary of earnings information during periods of increased market uncertainty. We find when the VIX is higher the media increase their coverage of earnings announcements relative to coverage outside of earnings announcements. This evidence is consistent with the media responding to increased demand for financial information during uncertain times. We find that such increases occur across different levels of the VIX, not just during the most extreme levels, and occur when increases in the VIX are attributable to changes in economic policy uncertainty, foreign currency volatility, and other sources of market uncertainty. We also find that the media trade off how they cover firms in response to market uncertainty. The increase in media coverage is most pronounced for short news flashes that can quickly but briefly disseminate new information. Full length articles, in contrast, decline. The increase in media coverage is also greater for bellwether firms and less for non-bellwether firms. In contrast to the media expanding its role as an information intermediary during uncertain times, we find little evidence that other providers of information increase their supply of information at earnings announcements. Firms do not change the frequency of their disclosures and financial analysts reduce the number of their forecast revisions.

We also find that the increased media coverage of earnings announcements during periods of higher market uncertainty leads to greater trading volume for both retail and institutional investors, larger price reactions, narrower spreads and greater depth, and greater intraperiod timeliness. These changes are in sharp contrast to the overall worsening of capital market outcomes that occur during periods of higher market uncertainty. In addition, these changes are in contrast to the effect of firm-initiated disclosure, which we fail to find alter capital market outcomes, and analyst forecast revisions, which decline in frequency and result in even worse capital market outcomes at earnings announcements.

These findings provide important new insights into how changes in aggregate market uncertainty alter the media's timing, content, and dissemination of information to market participants and how these changes improve capital market outcomes at earnings announcements. In addition, these findings provide insight into how the media makes trade-offs in coverage during periods of elevated market uncertainty. These findings also provide insight into how different providers of information—firms, analysts, and the media—alter their behavior and influence capital market outcomes when there is higher market uncertainty.

Appendix A

The variables for each empirical analysis are described in detail below.

Variable	Description
$LCoverage_{EA}$	The natural logarithm of one plus the number of news articles with relevance scores greater than or equal to 90 captured by RavenPack on days $[0, +1]$ relative to the quarterly earnings announcement
$LCoverage_{EA,Flash}$	The natural logarithm of one plus the number of news flashes with relevance scores greater than or equal to 90 captured by RavenPack on days $[0, +1]$ relative to the quarterly earnings announcement
$LCoverage_{EA,Orig}$	The natural logarithm of one plus the number of original news stories with relevance scores greater than or equal to 90 captured by RavenPack on days $[0, +1]$ relative to the quarterly earnings announcement
$LCoverage_{NonEA}$	The natural logarithm of one plus the average number of news articles with relevance scores greater than or equal to 90 captured by RavenPack during all two-day windows during the matched non-earnings announcement period
$LCoverage_{NonEA,Flash}$	The natural logarithm of one plus the average number of news flashes with relevance scores greater than or equal to 90 captured by RavenPack during all two-day windows during the matched non-earnings announcement period
$LCoverage_{NonEA,Orig}$	The natural logarithm of one plus the average number of original news stories with relevance scores greater than or equal to 90 captured by RavenPack during all two-day windows during the matched non-earnings announcement period
$\|AbnReturn\|$	The absolute value of raw return minus the CRSP value-weighted index return during the earnings announcement period $[0, +1]$
$AbnVol$	The share turnover during the earnings announcement period $[0, +1]$ less the median two-day share turnover of consecutive two-day periods during the non-announcement period, which is comprised of all dates between five trading days subsequent to the release date of quarter $t-1$ earnings and five trading days prior to the release of quarter t earnings
$AbnSpread$	The weighted average effective spread over trading days [0, +2] of the earnings announcement, where the weights are number of trades, minus the weighted average effective spread over trading days [−41,−11], multiplied by 100 (from Blankespoor et al., 2018)

Continued on next page

Appendix A continued

Variable	Description
$AbnDepth$	The natural logarithm of the weighted average bid and offer dollar depth over trading days [0, +2] of the earnings announcement, where the weights are time in force, over the weighted average bid and offer dollar depth over trading days [−41,−11] (from Blankespoor et al., 2018)
IPT_{Adj}	The speed with which earnings information is impounded into price, measured over the six-day earnings announcement window and adjusted for overreaction and subsequent reversal to the final cumulative abnormal return (from Blankespoor et al., 2018)
$AbnRetailVol$	The firm's daily average retail percentage of shares traded during days [0, +2] relative to the earnings announcement, minus the equivalent amount over days [−41, −11], multiplied by 100 (from Blankespoor et al., 2018)
$AbnNonRetailVol$	The firm's daily average non-retail percentage of shares traded during days [0, +2] relative to the earnings announcement, minus the equivalent amount over days [−41, −11], multiplied by 100 (from Blankespoor et al., 2018)
VIX	The average level of the Chicago Board Options Exchange Volatility Index during the period from five days following the announcement of quarter $t-1$ earnings to five days prior to the announcement of quarter t earnings
EPU	The average level of economic policy uncertainty index from Baker et al. (2016) during the period from five days following the announcement of quarter $t-1$ earnings to five days prior to the announcement of quarter t earnings
$OilVol$	The average level of oil price volatility during the period from five days following the announcement of quarter $t-1$ earnings to five days prior to the announcement of quarter t earnings
$CurrVol$	The average level of volatility of the seven currencies designated by the Federal Reserve Board as "major" currencies during the period from five days following the announcement of quarter $t-1$ earnings to five days prior to the announcement of quarter t earnings
VIX^{EPU}	The predicted value of VIX using EPU from a regression of VIX on EPU, $OilVol$, and $CurrVol$ (see Appendix B)
VIX^{OilVol}	The predicted value of VIX using $OilVol$ from a regression of VIX on EPU, $OilVol$, and $CurrVol$ (see Appendix B)
$VIX^{CurrVol}$	The predicted value of VIX using $CurrVol$ from a regression of VIX on EPU, $OilVol$, and $CurrVol$ (see Appendix B)
$VIX^{OtherUncert}$	Residual uncertainty from a regression of VIX on EPU, $OilVol$, and $CurrVol$ (see Appendix B)

Continued on next page

Appendix A continued

Variable	Description
$LForm8K$	The natural logarithm of one plus the number (two-day averaged number) of Form 8-K filings by a firm during the earnings (non-earnings announcement) window
$LRevisions$	The natural logarithm of one plus the number (two-day averaged number) of analyst earnings forecast revisions made during the earnings (non-earnings announcement) window
$AbsEarnSurp$	The absolute value of the seasonally adjusted change in earnings before extraordinary items scaled by market capitalization at the beginning of the fiscal quarter
$NegSurp$	An indicator variable equal to one if the seasonally adjusted change in earnings before extraordinary items is negative and zero otherwise
$LMktCap$	The natural logarithm of market value of equity
BM	Book value of stockholders' equity divided by market capitalization
$LFollow$	The natural logarithm of one plus the number of equity analysts following the firm during the most recent fiscal quarter
$InstHold$	Percentage of shares held by institutional investors
$IVol$	Annualized standard deviation of weekly residual returns based on the following model from Bandarchuk and Hilscher (2013): $r_{it} = a_i + b_i r_{mt} + \gamma_i r_{It} + e_{it}$
Ret	Buy-and-hold equity return during the previous twelve months
$SP500Member$	Indicator variable set equal to one if a firm is a member of the S&P 500 market index and zero otherwise
$LEmployee$	The natural logarithm of the number of employees
$LOwn$	The natural logarithm of the number of shareholders
$NasdaqTraded$	Indicator variable set equal to one if a firm's common shares trade on the NASDAQ and zero otherwise
$Turnover$	Average share volume divided by shares outstanding using daily stock market data over the last six months
$MomStrength$	Absolute value of the difference between the firm's stock return over the previous six months and the median stock return over the same period (Bandarchuk and Hilscher, 2013)
$Bellwether$	An indicator variable with a value of one if the explanatory power of various macroeconomic indices for a firm's earnings is in the upper quartile of the sample distribution (Bonsall et al., 2013), and zero otherwise
$Non-Bellwether$	An indicator variable with a value of one if the explanatory power of various macroeconomic indices for a firm's earnings is in the lower quartile of the sample distribution (Bonsall et al., 2013), and zero otherwise.

Continued on next page

Appendix A continued

Variable	Description
EarlyAnnouncer	An indicator variable with a value one if a firm's expected earnings announcement date is in the earliest quartile in a given fiscal quarter Savor and Wilson (2016), and zero otherwise
LateAnnouncer	An indicator variable with a value one if a firm's expected earnings announcement date is in the latest quartile in a given fiscal quarter Savor and Wilson (2016), and zero otherwise

Appendix B
Underlying sources of uncertainty driving the level of the VIX

The table below provides the results from the estimation of a time-series regression of VIX on economic policy uncertainty from Baker et al. (2016) (EPU), oil price volatility ($OilVol$), and the average volatility of the seven currencies designated by the Federal Reserve Board as "major" currencies ($CurrVol$) using monthly-level observations during our sample period of November 2005 through December 2013. Each variable is a significant determinant of the VIX and combined the variables explain 89.7 percent of the variation in VIX. The predicted values, denoted VIX^{EPU}, VIX^{OilVol}, and $VIX^{CurrVol}$, respectively, along with the residual, denoted $VIX^{OtherUncert}$, are used in place of VIX in Panel B of Table 3.

	(1) VIX
EPU	0.0197**
	(2.20)
$OilVol$	0.1637**
	(2.56)
$CurrVol$	1.9470***
	(7.31)
Constant	-8.2803***
	(-5.09)
Observations	98
Adjusted R^2	0.897

T-statistics are shown in parentheses below estimated coefficients and use Newey and West (1987) standard errors with four lags. *, **, and *** indicate two-sided statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

Figure 1: The VIX and underlying sources of market uncertainty

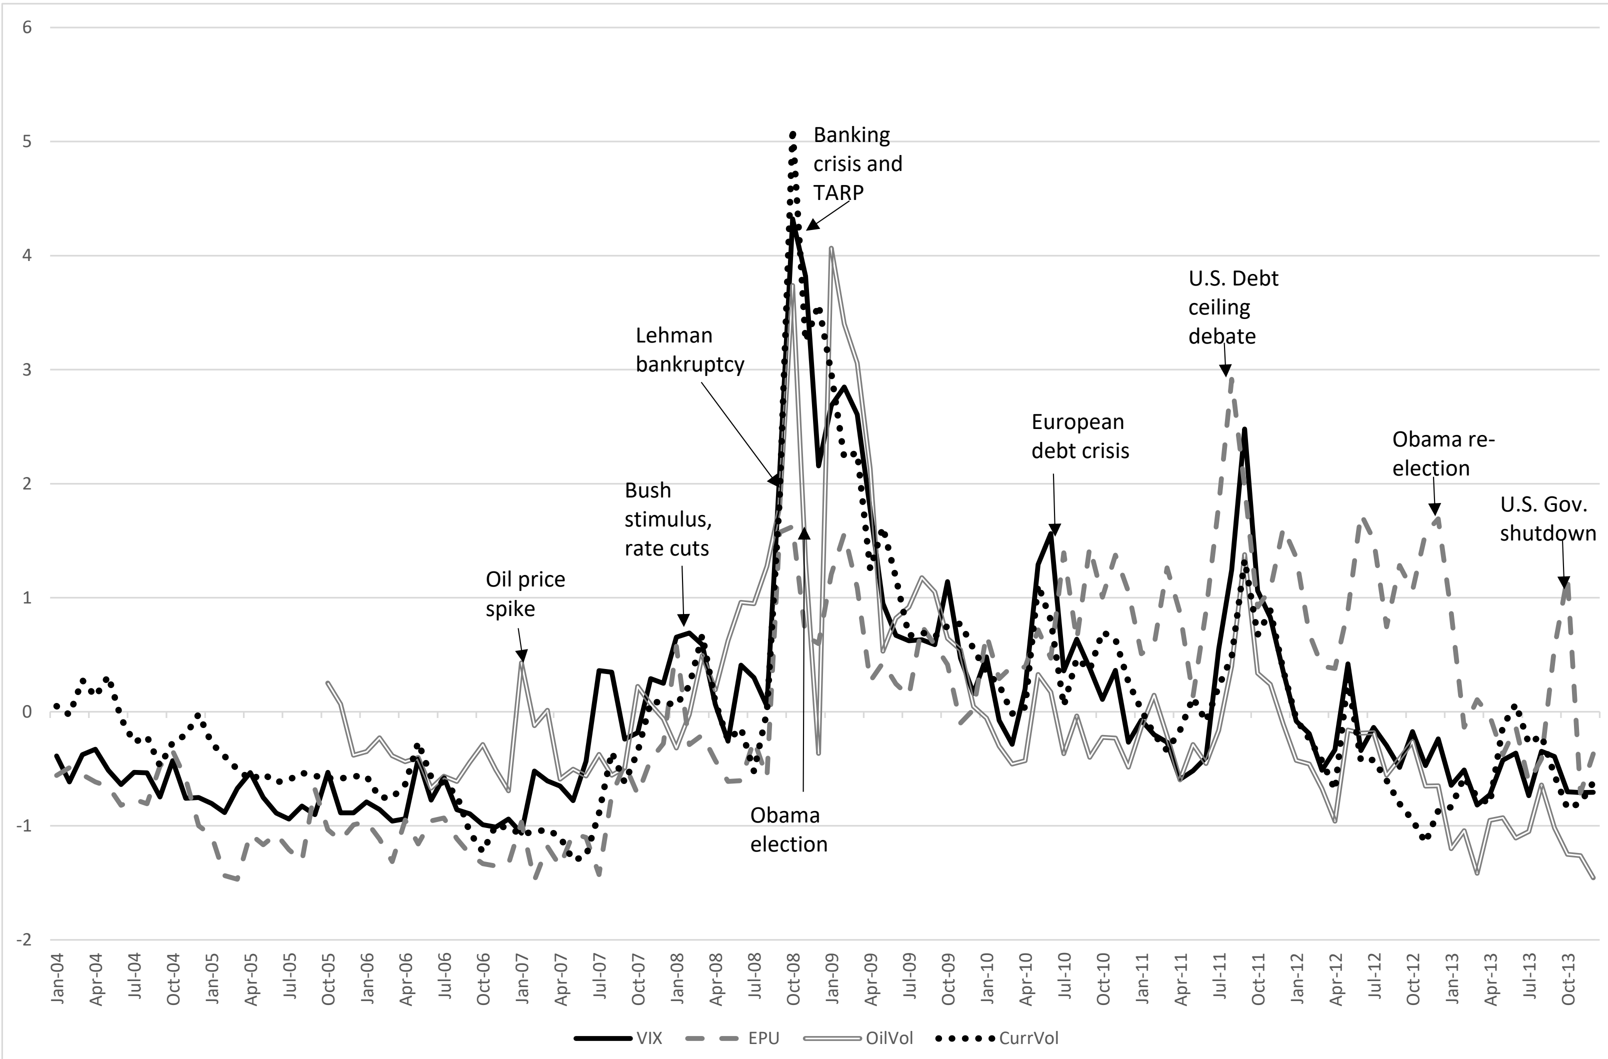

Figure 1 plots the month-end options volatility index (VIX), economic policy uncertainty index (EPU), crude oil price volatility index (OilVol), and average currency volatility index (CurrVol). All indices are standardized.

Table 1 presents descriptive statistics for the samples and variables used in the analysis. The descriptive statistics are for quarterly earnings announcements from 2004 to 2013 from Compustat, equity market information from CRSP, news stories from RavenPack, and intraday trading and price information from the NYSE's Daily TAQ database. All variables are defined in Appendix A.

Adjusted R^2	0.758	0.771	

Table 2 examines the relationship between market uncertainty (VIX) and media coverage. Panel A presents path analysis of the association with firm-initiated disclosures ($LForm8K$) and analyst forecast revisions ($LRevisions$) as mediator variables. Panel B presents regression results from the estimation of 1 using ordinary least squares. The analyses in both panels include results for an earnings-announcement period sample (as well as for a non-earnings-announcement period sample for comparison). The dependent variable, $LCoverage_X$, is the natural logarithm of one plus the number of news stories for a firm on the day of or the day after a quarterly earnings announcement ($X = EA$) or the average during all two-day windows during the matched non-earnings announcement period ($X = NonEA$). The sample period covers quarterly earnings announcements from 2004 to 2013 and corresponding non-earnings announcement periods. All other variables are defined in Appendix A. Column (3) reports the statistical test of the difference between the estimated coefficients on VIX in columns (1) and (2) using a stacked regression model. T-statistics are shown in parentheses below estimated coefficients and use standard errors that are clustered two-way by firm and year-quarter. *, **, and *** indicate two-sided statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

Table 3: Abnormal media coverage of earnings announcements and market uncertainty: What levels of the VIX and sources of uncertainty underlying the VIX are most important?

VIX^{EPU}=$VIX^{OtherUncert}$	4.96***		-1.26		5.13***	

Table 3 presents more detailed analyses of the relationship between market uncertainty (VIX) and media coverage. Panel A presents results from a piecewise model across sample quartiles of market uncertainty. Panel B presents results from the estimation of a modified version of 1 with predicted components of VIX (all variables are standardized) using economic policy uncertainty from (Baker et al., 2016) (VIX^{EPU}), oil price volatility (VIX^{OilVol}), and the average volatility of the seven currencies designated by the Federal Reserve Board as "major" currencies ($VIX^{CurrVol}$) included as regressors of interest in place of VIX. The residual value of VIX ($VIX^{OtherUncert}$) is also included as a regressor. See Appendix B for the estimation of VIX onto EPU, $OilVol$, and $CurrVol$. The dependent variable, $LCoverage_X$, is the natural logarithm of one plus the number of news stories for a firm on the day of or the day after a quarterly earnings announcement ($X = EA$) or the average during all two-day windows during the matched non-earnings announcement period ($X = NonEA$). All other variables are defined in Appendix A. In Panel A, the sample period covers quarterly earnings announcements from 2004 to 2013 and corresponding non-earnings announcement periods. In Panel B, the sample period covers quarterly earnings announcements from November 2005 to December 2013 and corresponding non-earnings announcement periods. Columns (3) report the statistical tests of differences between the estimated coefficients in columns (1) and (2) using a stacked regression model. T-statistics are shown in parentheses below estimated coefficients and use standard errors that are clustered two-way by firm and year-quarter. *, **, and *** indicate two-sided statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

Table 4 presents path analysis results from estimating the role of media coverage of other earnings announcements in crowing out the media coverage of firms' non-earnings announcement periods. The path analysis uses the amount of other firms' earnings announcement coverage ($LCoverage_{EA,Other}$), firm-initiated disclosures ($LForm8K$), and analyst forecast revisions ($LRevisions$) as mediator variables. The dependent variable, $LCoverage_{NonEA}$, is the natural logarithm of one plus the average number of news stories for a firm during all two-day windows during the non-earnings announcement period. The sample period covers firm-quarter observations from 2004 to 2013. All other variables are defined in Appendix A. T-statistics are shown in parentheses below estimated coefficients and use standard errors that are clustered two-way by firm and year-quarter. *, **, and *** indicate two-sided statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

Table 5: Abnormal media coverage of earnings announcements and market uncertainty: Does the media shift to specific types of news stories and firms?

Table 5 presents results from estimating the association between market uncertainty (VIX) and different types of media coverage. Panels A and B presents path analyses of the association for news flashes and original articles with firm-initiated disclosures ($LForm8K$) and analyst forecast revisions ($LRevisions$) as mediator variables, respectively. Panel C presents path analysis of the association with firm-initiated disclosures ($LForm8K$) and analyst forecast revisions ($LRevisions$) as mediator variables and bellwether status as a moderator based on the R^2 from a regression of firm earnings on several macroeconomic series (Bonsall et al., 2013) with $Bellwether_{High}$ and $Bellwether_{Low}$ defined as indicators for firms in the upper and lower quartiles of the sample R^2 distribution. Panel D presents path analysis of the association with firm-initiated disclosures ($LForm8K$) and analyst forecast revisions ($LRevisions$) as mediator variables and with earnings announcement timing as a moderator based on firms' predicted earnings announcement timing with $EarlyEA$ and $LateEA$ defined as indicators for firms in the upper and lower quartiles of earnings announcement timing for a fiscal quarter. The analyses in all panels include results for an earnings-announcement period sample (as well as for a non-earnings-announcement period sample for comparison). The dependent variable $LCoverage_{X,Flash}$ ($LCoverage_{X,Orig}$) is the natural logarithm of one plus the number of news flashes (original articles) for a firm on the day of or the day after a quarterly earnings announcement ($X = EA$) or the average during all two-day windows during the matched non-earnings announcement period ($X = NonEA$). The sample period covers quarterly earnings announcements from 2004 to 2013 and corresponding non-earnings announcement periods. All other variables are defined in Appendix A. Column (3) reports the statistical tests of differences between the estimated coefficients in columns (1) and (2) using a stacked regression model. T-statistics are shown in parentheses below estimated coefficients and use standard errors that are clustered two-way by firm and year-quarter. *, **, and *** indicate two-sided statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

Table 6: Market uncertainty and abnormal earnings-announcement return volatility and trading volume: The mediating influence of media coverage

z-test: (I) = (III)	2.49**		2.50***	

Table 7 presents path analysis results from estimating the mediating role of media coverage ($LCoverage_{EA}$) on the association between market uncertainty (VIX) and earnings announcement liquidity and price efficiency. The sample period covers quarterly earnings announcements from 2004 to 2013. The Panel A analyses investigate information asymmetry; the dependent variables are *AbnSpread*, the weighted average effective spread over trading days [0, +2] of the earnings announcement, where the weights are number of trades, minus the weighted average effective spread over trading days [−41,−11], multiplied by 100, and *AbnDepth*, the natural logarithm of the weighted average bid and offer dollar depth over trading days [0, +2] of the earnings announcement, where the weights are time in force, over the weighted average bid and offer dollar depth over trading days [−41,−11] (Blankespoor et al., 2018). The Panel B analysis investigates price efficiency; the dependent variable is IPT_{Adj}, the speed with which earnings information is impounded into price, measured over the six-day earnings announcement window and adjusted for overreaction and subsequent reversal to the final cumulative abnormal return (Blankespoor et al., 2018). The Panel C analyses investigate abnormal trade by retail and non-retail traders; the dependent variables are *AbnRetailVol*, the firm's daily average retail percentage of shares traded during days [0, +2] relative to the earnings announcement, minus the equivalent amount over days [−41, −11], multiplied by 100, and *AbnNonRetailVol*, the firm's daily average non-retail percentage of shares traded during days [0, +2] relative to the earnings announcement, minus the equivalent amount over days [−41, −11], multiplied by 100 (Blankespoor et al., 2018). The sample period covers quarterly earnings announcements from 2004 to 2013. All other variables are defined in Appendix A. T-statistics are shown in parentheses below estimated coefficients and use standard errors that are clustered two-way by firm and year-quarter. *, **, and *** indicate two-sided statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

ABSTRACT

This paper reviews the literature on capital markets research in accounting over the last 50 years. Rather than trying to be comprehensive, the review focuses on selected areas, and strives to be forward-looking. The first major takeaway is that the literature has made great progress, especially on the technical side. The second takeaway is that great opportunities remain, especially in using Big Data, looking more closely into the accrual process, and in issues related to standard setting.

1. Some caveats

I would like to start with some caveats. The first caveat is that this review is not meant to be comprehensive. The existing capital markets literature is simply too large, and so it is nearly impossible to cover everything. To use an analogy from music, what I am going to do here is to present the Selected Hits, rather than the Complete Collection. And since it is the Selected Hits, the choice of what to include is largely driven by personal choice and personal expertise. The idea is to provide a breezy and punchy overview rather than an exhaustive analysis of everything that has been done. Second, I will be attempting to "give an opinion" rather than just "listing what has been done". In other words, the review will take more of a position on certain things. Note that my opinion could be biased or wrong but I feel that this is the right occasion to say something more pointed rather than keep to the safety of just listing accomplishments. Third, the review aims to be big-picture and forward-looking. The important thing is not only what we have done so far but where we go from here. Accordingly, I will try to provide some ideas for future research.

For those who want a more complete coverage, there are some existing reviews of the capital market literature that are helpful. Kothari (2001) is a comprehensive review of capital markets research; it is widely read and cited but it does not reflect more recent findings. Richardson et al. (2010) is more recent but covers mostly

accounting anomalies and fundamental analysis. Dechow et al. (2014) is also recent and more compact, concentrating mostly on the relation between stock prices and earnings. The most recent review I have seen is Kothari and Wasley (2019), a fairly comprehensive review with a particular emphasis on how the literature evolves from Ball and Brown (1968).

2. Is the earnings number useful?

2.1. An updated replication of Ball and Brown (1968)

Ball and Brown (1968) is widely considered foundational for the capital market literature, tracking the stock returns for separate portfolios of positive and negative earnings surprises. The idea is that the stock market is an efficient aggregator of information, and therefore we can use stock prices and returns as a benchmark for the information content in earnings. Fig. 1 shows an updated replication of Ball and Brown (1968), reproduced from Dechow et al. (2014). An examination of Fig. 1 reveals pretty much the same message as the original Ball and Brown (1968) paper, showing that stock returns correctly anticipate the sign of future earnings surprises up to 12 months in advance. If anything, the spread between the positive and negative portfolio is wider here, exceeding 30% over the full 18-month window. Thus, the original message of Ball and Brown (1968) is emphatically confirmed in more recent samples, showing the continued relevance of their groundbreaking research. The other big takeaway is that there appears to be a market underreaction to earnings information, as the two portfolios continue to drift in the direction of the earnings surprises even after earnings are announced in month 0. This phenomenon was heavily studied in later research, and became known as the Post-Earnings-Announcements-Drift (PEAD).

2.2. Are earnings announcements useful?

The other major study from the early years is Beaver (1968), which shows pronounced spikes in trading volume and stock returns in narrow windows around earnings announcements. This evidence indicates that earnings announcements contain new information, and that the stock market reacts to this new information. Fig. 2 presents the Dechow et al. (2014) replication of Beaver (1968) for several sample periods over time. What is interesting here is that both the trading volume and the stock return reaction have become more pronounced over time. So, it seems that earnings announcements have become a source of increasing information content, although more recent studies find that this information content is due to items beyond earnings (Beaver et al., 2020).

Summing up, early studies like Ball and Brown (1968) and Beaver (1968) marked an exciting start to capital market research in accounting. Earnings especially, and the outputs of the accounting system more generally,

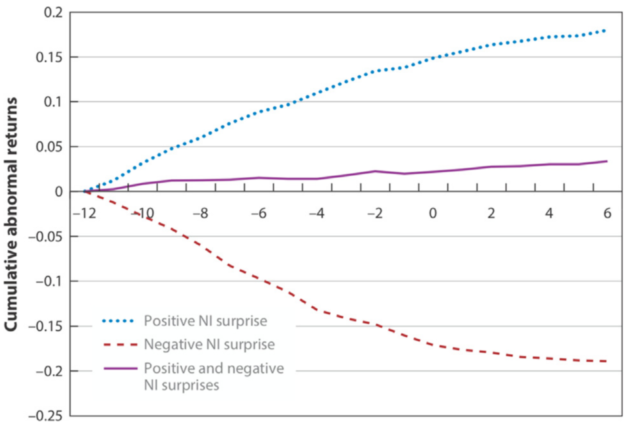

Fig. 1. Month relative to annual earnings announcement.

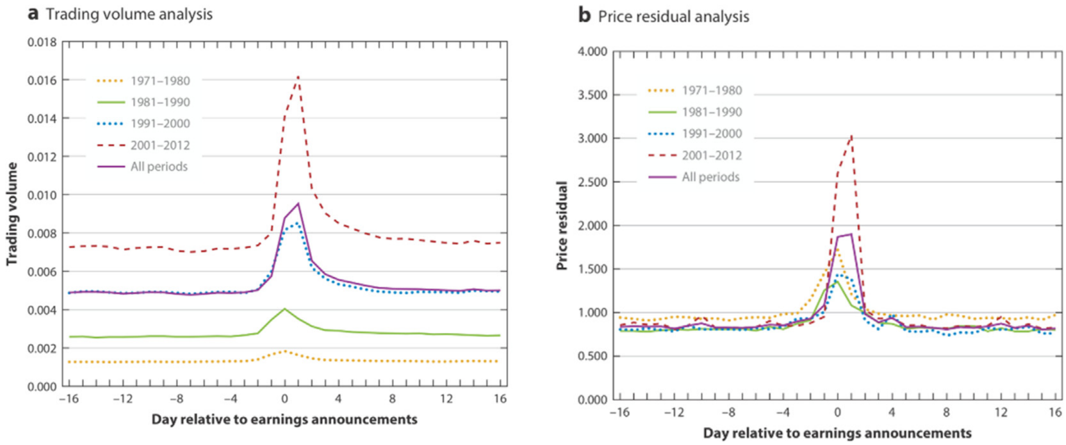

Fig. 2. Day relative to earnings announcements.

seemed to be a powerful source of information for capital markets. Accordingly, this early excitement and promise attracted many researchers, and capital markets quickly became perhaps the dominant area in all accounting research.

2.3. *After Ball and Brown (1968) and Beaver (1968)*

I use the framework and the language of *The Structure of Scientific Revolutions* by Thomas Kuhn to describe what followed the initial successes in capital markets research, as the comparison is apt. Basically, the early studies marked the rise of a new paradigm which captured the minds of accounting academics, and the whole idea and practice of accounting research shifted in a decisive manner. While previous research relied mostly on "armchair" arguments and speculations, the new paradigm brought empirical tests and evidence to the fore, with corresponding attention to data, statistical tests, and borrowing theories and methods from economics and finance. There were some interesting sociological angles as well, with many from the older generations displaced or sidelined by the new way of doing research.

Using the language of the Kuhn book, a great volume of "normal" research on the price/earnings relation appeared after the initial foundational studies. "Normal" research means "mopping up operations", basically studies that explore and advance the new paradigm but do not aim for radical novelty. The basic point of Ball and Brown (1968) and Beaver (1968) is that prices react to earnings, and earnings have information content. But there was a lot that could be done with these initial findings, they could be expanded to new samples, improve the test methodology, and so on. For example, the normal research on the price/earnings relation includes multiple studies on the specification of earnings surprises, such as using time-series models vs. analysts forecasts. Researchers explored event return windows that varied from a few days to several years, and used various definitions of earnings, such as net income, income before non-recurring items, and cash flows.

One useful way to summarize the first two decades of capital market research is provided by Lev's (1989) influential review. Looking at the big picture, Lev (1989) finds that the whole exercise has been somewhat disappointing, especially compared to the enormous effort invested in this literature. His main point is that if we look at the magnitudes of the R^2 of the associations between earnings numbers and returns, they are fairly small, with typical magnitudes of 2–7%. There are, of course, good reasons for this, a major one being that stock returns are very noisy. Thus, the question is how much R^2 can we expect, especially on a firm-level basis where the noise is much higher as compared to portfolio specifications. Lev (1989) also suggests that GAAP rules are probably at fault as well, and perhaps we need to think of ways to improve the accounting to better capture the value of firm operations.

Perhaps even more importantly, around the end of the 1980s and the beginning of the 1990s, the profession came to the critical realization that the basic premise of using formulations like $R_t = a + b^*\Delta E_t + e$ is quite limiting (Lee, 2001). Notice that we are using market prices or returns as the benchmark, and we judge information content in earnings by the degree to which the right-hand side maps into this benchmark. The problem is that if we always put contemporaneous returns on the left-hand side in these models, we are assuming that the market has already perfectly impounded all available information. But if the market perfectly knows everything already, what is the use of accounting? Where is our value-added then? Does it matter at all how we do the accounting?

3. The rise of fundamentals-based research

There was another new wave of research that soon arose in response to these disquieting questions, and I do think it was very good for accounting. This is the rise of what we can call fundamentals-based research. The critical difference from before is that instead of immediately going to the market for validation of accounting information, we now first study the accounting system itself, and try to understand how it captures the value created in real company operation, including the production of key value metrics like earnings and book value. And it is only after we internalize this knowledge that we turn to the market to see if the fundamentals-based metrics map into observable market prices. It was a very definite and large shift in the way that we think about these things. Perhaps most prominently, James Ohlson and Stephen Penman led the way here in a series of theoretical papers, developing these ideas more formally, see Ohlson (1995) for example. Basically, the idea is to derive equity value as a function of firm fundamentals, especially earnings and book value of equity. And soon after, there was a stream of empirical papers implementing these ideas, prominent examples include Frankel and Lee (1998) and Dechow et al. (1999).

This shift in thinking opened the doors to asking entirely new questions, and addressing new audiences. For example, if we find that fundamental values and observable stock prices differ, now we are not going to necessarily assume that prices are better, and accounting inputs are deficient. Now we may allow for the possibility that prices are deficient, and we may investigate whether prices catch up with fundamental value at some point, consistent with how value investors like Warren Buffett approach the analysis of financial information and make investments. Correspondingly, such research has natural synergies with our teaching, where a lot of our undergraduate and MBA students have an interest not so much in accounting itself but more in how accounting can be used to find hidden value, and lead to better investing decisions. In other words, this new thinking marked a radical shift where market efficiency is now an examined hypothesis rather than just a maintained hypothesis.

Perhaps the biggest single positive from the rise of fundamentals-based research is that this new approach sparked renewed interest in how accounting actually works. I view this as a strong positive because it naturally plays to our expertise in accounting, and allows us to offer insights which would otherwise not be possible for our colleagues in finance and economics who study similar questions. It basically brought us back to such classic questions as "What makes good accounting?" and "What makes earnings useful?".

4. What makes earnings useful?

4.1. Accrual accounting

Dechow (1994) is the paper that both signaled and catalyzed the rebirth of interest in how accrual accounting actually works. It is remarkable that Dechow (1994) appeared a full 26 years after Ball and Brown (1968), while it asks the most basic questions about accrual accounting. Most prominently, is earnings or cash flows better at measuring firm performance? The story in Dechow (1994) is that cash flow accounting is simple and objective: income is just cash flows coming in, while expenses are cash flows going out. But the weakness of cash flow accounting is that there are timing and mismatching problems, which question the use of net cash flow as a measure of firm performance. For example, consider a firm that sells Christmas trinkets. Before the Christmas season, the firm spends a lot of money on inventory, and then the money from the Christmas sales comes much later. So, if we look at the performance of this firm in terms of net cash flow, it looks like it has a lot of losses first and then it makes big profits later on. This does not make much sense because the "early losses" are clearly related to the "late profits" by the logic of the business.

Accrual accounting alleviates such timing and mismatching problems through the use of accruals. Using accruals, the Christmas trinkets firm above will capitalize the cost of inventory, and expense it in Cost of Goods Sold when the inventory is sold. Thus, accrual accounting aligns the cost of Inventory with Sales, consistent with the logic of the business, and so we get a much better measure of firm performance. But the cost of using accrual accounting is that accruals are essentially estimates made by management, which opens the door to estimation errors and subjectivity, and even willful manipulation. For example, capitalizing the cost of inventory at the time of purchase in anticipation of realizing it as Cost of Goods Sold at the time of sale may turn out to be problematic because we may need to write off the inventory before selling it. Thus, recording accruals involves a trade-off of benefits and costs, and it is an empirical question whether the sophistication of accrual accounting is better than the simplicity and objectivity of cash flow accounting.

Using stock prices as the benchmark for value-relevance, Dechow (1994) finds that accrual earnings are more strongly associated with stock returns than cash flows. In other words, the findings of Dechow (1994) indicate that accrual accounting is indeed resolving timing and mismatching problems, and that the stock market understands and endorses the use of accrual accounting. Thus, Dechow (1994) is foundational in terms of establishing the utility of accrual accounting.

A continuation of this line of inquiry is Dechow and Dichev (2002), delving further into the structure of the accrual process. The first message of Dechow and Dichev (2002) is captured in Eq. (1) below, where accounting earnings is expressed as a sum of past, present, and future cash flows, and the origination and reversals of accrual estimation errors. In Eq. (1), the first three terms are the cash flows, where the subscripts indicate when the cash flow occurs, and the superscripts indicate when the cash flow is recognized in earnings. The intuition is that accruals resolve the timing and mismatching problems in the underlying cash flows by moving their recognition in earnings across time, e.g., the revenue from a sale is recognized in earnings at the time of the sale by recording an accounts receivable rather than waiting for sales proceeds to be collected later on. Thus, the benefit of accrual accounting is captured in the first and third cash flow terms, whose recognition in earnings has been shifted across time. However, the benefit of recording accruals comes at the cost of incurring accrual estimation errors, e.g., the recorded Accounts Receivable estimate may be less than the actual cash collections later on. The consequence is that recording an overstated receivable first and writing it off later introduces noise in earnings, creating a false boost in earnings first, and a false decline in earnings later on. In sum, the cash flow terms capture the benefit of accrual accounting, while the error terms capture the cost. For accounting to be "good", we hope that the cash flow terms are large, and the error terms are relatively small.

$$Earnings_t = CF^t_{t-1} + CF^t_t + CF^t_{t+1} + \varepsilon^t_{t+1} - \varepsilon^{t-1}_t \tag{1}$$

Since moving the recognition of cash flows into earnings across time is accomplished by recording accruals, Dechow and Dichev (2002) also show how accruals can be expressed in terms of the underlying cash flows. Unfortunately, the current accounting system does not provide the theoretically required cash flow variables, and instead the empirical version of Dechow and Dichev's model is based on observable variables. Since the model is based on working capital accruals, not surprisingly the empirical version employs cash flow from operations (see Dechow and Dichev, 2002 for further detail):

$$Accrual_t = b_0 + b_1 CFO_{\mathrm{t}-1} + b_2 CFO_{\mathrm{t}} + b_3 CFO_{\mathrm{t}+1} + \boldsymbol{e} \tag{2}$$

Intuitively, Eq. (2) says that accruals that do not map into their corresponding cash flows represent the accrual estimation errors, e.g., the portion of receivables not eventually collected represents the initial overstatement of the receivable. The empirical tests in Dechow and Dichev (2002) show that the estimates of the accrual estimation errors derived from Eq. (2) are indeed helpful in capturing the quality of accruals and earnings, e.g., high levels of estimation errors are related to low earnings persistence.

While the Dechow and Dichev (2002) model has been widely used, it also has some limitations. So, how can we improve on it? Useful extensions and re-formulations include McNichols (2002), Francis et al. (2004, 2005), Ball and Shivakumar (2006), and others. For example, McNichols (2002) combines the Dechow and Dichev (DD) model with the Jones (1991) model, and that combination has been popular empirically, although it is more questionable on theoretical grounds. I would argue that further work is possible here. Most importantly, notice that the DD model only captures the discretion/estimation of anticipatory accruals mapping into future cash flows (like Accounts Receivable). But there is a lot of other discretion/estimation in accounting, including depreciable and useful lives, salvage values, interest rates, sales returns, percentage of completion, etc.

The good news is that the basic DD intuition applies to these other estimates as well. The spirit of the DD model is that accounting makes estimates, and the resulting estimation errors represent the cost of using accruals, manifesting as noise in earnings. The very same intuition applies to all other estimates as well, and so it can be used to measure the accrual estimation error noise as well. If you have the estimates, and if you have the realizations, the difference between them will give you the estimation errors. For example, if initial estimates of severance costs are too high and are low at realization, earnings will be initially understated and then overstated at realization. The bad news is that in most cases the accrual estimates and their realizations are not available to outside users of financial information.

But perhaps there could be some workarounds in implementing this intuition. For an idea what is possible, notice that the error term in Eq. (1) has a very specific form. If you re-write Eq. (1) as of time t − 1, and also as of time t + 1, and compare that to the expression as of time t, you would see that the error term is very strongly negatively correlated across time. This negative relation is, of course, not accidental. The error terms in (1) are negatively autocorrelated because the accrual process is self-correcting - if you make an accrual error in some period, it has to be corrected in some future period with an accrual with the opposite sign. The DD model is on working capital, so the errors and their corrections happen within one period, e.g., if at time t the initial estimate of the Accounts Receivable is too optimistic, the uncollected receivable is written off at time t + 1. The initial overestimation has a positive effect on earnings, and the write-off has a negative effect on earnings, so the accrual estimation errors are negatively autocorrelated over time. The same intuition applies to all other estimates. If we make an accrual estimation error, we have to correct it at some point after that with an accrual with the opposite sign. Thus, the signature of accrual estimation errors is that they reverse over time, and thus they induce a negative autocorrelation in earnings. The challenge will be to formalize this intuition, and to distinguish the reversals of all accruals (since all accruals have to reverse at some point) from the reversals of accrual estimation errors. To my knowledge, Dechow et al. (2012) is the only existing study that uses this intuition but I believe that we can get a lot more mileage out of it.

There are many other worthy studies on the properties of accruals but for the purposes of this review, I will limit the discussion to just two more widely influential examples. Sloan (1996) examines Eq. (3) below, and finds that the coefficient b_1 is greater than b_2, indicating that the cash flow component of earnings is more persistent than its accrual component. In other words, the results in Sloan (1996) indicate that firms with high accruals have low earnings persistence, and low earnings quality.

$$E_t + 1 = b_0 + b_1 * CFO_t + b_2 * Accruals_t + e \tag{3}$$

In addition, investors do not seem to understand this property, so portfolios long on stocks with low accruals and short on stocks with high accruals earn abnormal returns on the magnitude of 10% a year. This phenomenon has become known as the "accrual anomaly," and is one of the most widely known and researched stock market anomalies during the last 25 years.

Richardson et al. (2005) extends Sloan (1996), and investigates for differential persistence *within* accruals. The idea is that looking closer at the properties of the accrual process allows one to identify accruals that are more problematic than other accruals. Indeed, Richardson et al. (2005) identify a taxonomy of accruals that is helpful in predicting earnings quality, and also find that the stock market does not seem to fully appreciate these more subtle properties of accruals. But the most important contribution of Richardson et al. (2005) really is that they provide a comprehensive definition of accruals, namely, for a given period accruals can be defined as the changes in all non-cash assets and liabilities during that period. To me at least, the fairly-recent arrival of Richardson et al. (2005) is totally fascinating. Accruals represent the value-added of accrual accounting in the world, the bread and butter of what we do. Yet it took almost 40 years of research after Ball and Brown (1968) to finally have a comprehensive definition of accruals! While there could be a pessimistic read on this fact, I prefer the more positive interpretation. If the Richardson et al. (2005) experience is any guide – and I think it is – it implies that there are a lot of fundamental discoveries still to be made, and it is only our own limitations that prevent us from seeing what they are. What are we going to do in the next 50 years? The good news is there seems to be a lot that can be done, and I try to provide some pointers further below.

4.2. Conservatism

Another major strand of the literature on what makes earnings useful is conservatism, starting with Basu (1997). The story there is that accounting reacts asymmetrically to good and bad news. Specifically, accounting immediately impounds the full effect of bad news, capitalizing the present value of all future implications. For example, on finding that the depreciable life of some asset turns out to be shorter than originally expected, accounting will immediately write down the asset for the full effect of this shortening. In contrast, the book values of assets are not written up under favorable circumstances, and the gain on value is delayed until the asset is sold.

The literature on conservatism has seen rapid growth, finding a number of beneficial effects of more conservative accounting, especially for contracting outcomes. Indeed, the sheer volume of the conservatism literature warrants a separate review in itself, and such reviews actually already exist (Basu, 2009). So, instead of attempting to survey this literature, I would like to make one limited but crucial point. The Basu (1997) measure of conservatism uses stock returns as the benchmark for information content, and stock returns reflect many things, including possibly other explanations for the hypothesized asymmetric relations with earnings. Correspondingly, the Basu measure has been subject to a number of criticisms, and then rebuttals, see for example, Ball, Kothari, and Nikolaev (2013) and references thereof. Personally, I think a possible way forward in this literature is to derive a measure of conservatism which is independent of market prices, essentially a fundamentals-based measure of conservatism.

4.3. The dark side of discretion – earnings management

Earnings management can be defined as intentional adjustments to reported earnings to achieve desirable outcomes such as beating earnings benchmarks. By its very nature, earnings management is harmful to the role of earnings as a measure of firm performance and, correspondingly, research in this area has been a major focus for accounting academics for many years. By now, earnings management represents a very large, and rather mature literature, comprising dozens and perhaps even hundreds of studies.[1] Without getting into detail, I think the weight of the evidence leaves little doubt that earnings management exists. The extent of it, though, is more debatable, and partly depends on definition. It seems that more innocuous forms of earnings management within GAAP rules are widespread, affecting about 20% of U.S. firms in recent years (Dichev et al., 2013). More serious and extreme forms of earning management crossing into fraud seem to be much less prevalent, perhaps on the magnitude of 1–2% of firms, as reflected in studies of formal SEC actions and investor lawsuits (Dechow et al., 2011).

Is there room for more work in this literature? Given the sheer number of existing studies, it has become more difficult to make a meaningful contribution. On a personal level, I think two areas offer room for improvement. First, we need more earnings management studies where the null hypothesis is defined in a much sharper way as compared to that for most existing research. The null hypothesis is a statement of what earnings would be without earnings management. And this is really the key weakness of the majority of studies here: it is not quite clear whether the null is sharply defined enough to offer a powerful test. For example, suppose that there is a study which finds that in bad times managers cut R&D, apparently to hit earnings benchmarks. The question, though, is whether such a finding is truly indicative of earnings management - because in bad times prudent managers would cut R&D down anyway, as they should. So, what is the key to a sharp null hypothesis? There could be different approaches here but basically the key is identifying a setting where the null of no earnings management is very clear and convincing.

Second, it would be good to have more big-picture evidence on the economic prevalence of earnings management. By now there are scores of studies that offer evidence of earnings management in certain settings like equity offerings or for certain earnings components like special items or accruals. But there is less evidence on the broad prevalence of earnings management in the economy. Some authors opine that earnings management

[1] In fact, this literature has been such a major preoccupation of accounting research that one can argue that we have been more successful at identifying the problems of accounting (of which earnings management is a major one) rather than building up the case for what is good in accounting.

is likely confined to isolated pockets of rogue managers and firms, while others suggest that it is a rather pervasive phenomenon affecting perhaps the majority of firms in one way or another. More research could help to narrow down these rather divergent views.

4.4. Fair value

The research on fair values is another significant stream of the literature that investigates what makes accounting numbers useful. The reason is that the U.S. and international standard setting has adopted a balance sheet view of accounting, which emphasizes the valuation of assets and liabilities as the primary role of accounting. An integral part of this view is a broad push for various forms of fair value accounting, especially for financial assets and liabilities. Accordingly, there have been a number of studies that investigate the information content of fair values, usually benchmarking them against stock prices. Barth (1994) finds that the fair values of investment securities of banks provide significant information content beyond that of historical costs. For bank loans, Barth et al. (1996) also documents significant information content for fair values but Eccher et al. (1996) and Nelson (1996) arrive at the opposite result.

Some studies investigate the value relevance of fair values stratified by their reliability. Specifically, existing GAAP establishes the fair value hierarchy of using the so-called Levels 1, 2, and 3 inputs, where Level 1 includes the most cleanly measured assets like regularly traded shares on organized exchanges, and Level 3 includes the most problematic assets such as mortgage-backed securities and private equity shares. The prediction is that assets which are measured more cleanly will likely have more value relevance. This prediction seems intuitive, and is confirmed in the research findings (Choi et al.; Kallapur and Kwan, 2004; Song et al., 2010). The European setting provides some decisive advantages for research in fair values, specifically IFRS allows some PPE-type assets to be revalued up, which is not allowed under U.S. GAAP. The main finding in the European setting is that such upward asset revaluations do map into stock prices, which suggests that they have value relevance (Aboody et al., 1999).

Overall, it seems that fair values are reliably informative for financial assets and liabilities but the picture is more complicated and contentious for operating assets and liabilities. Of course, a key explanation for this difference is that financial assets typically have exchange value independent of the value of the firm and its operations, while operating assets are by definition mostly for synergistic use within the firm.

4.5. The big picture on the usefulness of accounting

In trying to make sense of the accumulated evidence, it is useful to step back and think about the big picture on the usefulness of accounting. The key question here is: what do investors think about the key outputs of accounting? Overall, there is some very good news here. Crucially, investors still consider earnings the single most important number in making their decisions (Graham et al., 2005). So, we can take some comfort in the fact that, despite all problems like earnings management and complicated accounting rules, we still produce the number that is the most used by investors.

But there's also some not-so-good news. There is solid evidence that earnings volatility has doubled or tripled over the last 30–40 years, and earnings persistence is way down, from a near-random-walk of 0.90 down to 0.60 (Givoly and Hayn, 2000; Dichev and Tang, 2008), and perhaps even lower today. These findings are troubling because they question the traditional role of current earnings as a guide to future earnings. Given these results, it is probably not surprising that studies have also shown a sharp deterioration of the relation between stock returns and earnings over time (Collins et al., 1997). In addition, we see a proliferation in non-GAAP definitions of earnings, which suggests that investors are dissatisfied with GAAP earnings, and are looking for alternative and better measures of performance.

Is this deterioration of the information content of GAAP earnings due to changes in the GAAP rules or changes in the real economy? And what can be done about it? Dichev and Tang (2008) point to the increasing balance sheet orientation of GAAP rules as a possible explanation. The story is that this orientation produces frequent asset/liability revaluations, which appear as one-time items on the income statement, and reduce the otherwise high persistence of regular ongoing income. Donelson et al. (2011) confirm the importance of one-time items but find that it is mostly due to economic factors, while Srivastava (2014) points to the confounding effect of newly listed firms with lots of intangibles. Overall, this is an ongoing debate, and the difficulty is that the accounting and the economics are entangled with each other, so it is hard to cleanly separate their effects. Finally, more research in this area seems highly desirable because of its potential to inform GAAP standard setting.

5. A note on research methodology

In addition to discussing topics and areas of research, I would like to make a brief note on research methodology, using the earlier discussion of the post-earnings announcement drift as an illustration. The big positive is that when you look over the last 30 to 40 to 50 years, the general level of research proficiency is way up, there is just no doubt about it. The younger generations are much more tooled up in terms of statistics and research methodologies, the PhD programs do a better job, the computer equipment is way better, the databases are also better. So, there is no doubt that the technical level is not just a little but significantly better over time. This is all a tremendous achievement, and a great portent for the future.

What, then, are the challenges? In short, a lot of research designs tend to be quite bland. The typical research paper today has some story and hypotheses, and basically what the test boils down to is a prediction that the coefficient on some variable is different from zero, say positive. And in the typical case, the coefficient does turn out to be significantly positive. Such results, however, are rather bland and unconvincing, or "do not change the priors much" if you want to use the scientific jargon. Why? For one thing, samples tend to be quite large nowadays, and that means that most variables show up as statistically significant at conventional levels. In addition, there are growing concerns about various forms of p-hacking and cherry-picking of the results. So, what can be done about this? At the very minimum, we have to be more proactive about establishing economic significance, in addition to statistical significance. That implies, for example, looking at incremental R^2 from including the relevant variable or not, and looking at the change in the dependent variable for a typical change in the independent variable. Formulating hypotheses on the magnitudes of the coefficient rather than just the sign is also a great way to go, while it is close to non-existent today.

I also think that the effort to avoid "accidental significance" should be broader than the minimums identified above. I would use one of my very favorite studies, Bernard and Thomas (1990), to illustrate what I am trying to say. Bernard and Thomas (1990) is a study on PEAD, so the basic story is that stock returns continue to drift in the direction of the earnings surprise for many months after the earnings announcement. So, a bland study in this space will be some kind of regression of the abnormal stock returns on the magnitude of the earnings surprises. But the Bernard and Thomas (1990) study is a lot more interesting, and consequently a lot stronger, than that. By advancing some sharper assumptions, Bernard and Thomas are able to make detailed and intricate predictions about the pattern of abnormal stock returns, including their ordered signs (three positives in a row, one negative), their relative magnitudes, and with the effects manifesting in narrow windows around subsequent earnings announcements. The bottom line is that at the end of that paper one is left with the strong impression that the documented pattern of results is highly unlikely to happen by chance. So, ideally, it would be great to see a lot more of that, sharper and more specific predictions about not just the sign of a coefficient but also about its magnitude, predictions on the pattern of results as opposed to just one result, the timing of the hypothesized effect, and so on. These are the kinds of characteristics that make for a convincing paper, and memorable results.

6. Some possible areas of future research

As Yogi Berra famously said "It's tough to make predictions, especially about the future." So, consider the following as partly a prediction of what is likely to happen, and partly as a personal wish list for what I would like to see happen.

6.1. Prediction of long-term earnings

The literature on valuation leaves little doubt that forecasting of long-term earnings is the key to deriving better estimates of value (Ohlson, 1995). And those who derive better estimates of value can then make better investing decisions, and earn positive abnormal returns. Given such indications of importance, surprisingly little has been actually done in this space. Most studies that use long-term earnings projections source them from analyst forecasts despite reliable evidence that such forecasts suffer from extreme optimism (McInnis, 2010). Perhaps the best explanation for this state of affairs is also the simplest - long-term prediction of earnings is just difficult. But the case for the value of long-term forecasting of earnings remains unchanged. Perhaps new data and new techniques can re-energize this line of inquiry (e.g., using machine learning).

6.2. Using big data, especially in fundamental analysis and valuation

Using Big Data in fundamental analysis and valuation is already happening, and will not only continue for a while but is almost surely here to stay. There are already a number of papers using various kinds of new and big data, including Glassdoor data on opinions from employees, online customer reviews, cellphone location data, crowdfunding data, photo, speech, and video data on managers, satellite images of parking lots and so on (Huang, 2018; Huang et al., 2020; Katona et al., 2018; Mayew and Venkatachalam, 2012). Further developments along these lines are basically unavoidable, and my guess is that they will happen sooner rather than later.

For those who are looking to get involved in this area, the basic template for research is fairly clear. You look for some new data like employee satisfaction or satellite data on whether parking lots are full. Based on this data, you try to establish some links to future fundamentals (especially earnings), and then you try to see whether this fundamental relation is priced correctly in the capital markets. In other words, at least conceptually, the basic template is fairly straightforward. The challenge is more on the technical side, in learning to program and to manipulate very large datasets or unusual and ill-behaved data. The upshot is that those who are willing and able to make the sizable investment to operate in this area are likely to be well-positioned for the future.

6.3. Paying more attention to the accrual process

The accrual process is our value-added to the world. We need to thoroughly understand and own this space to make a meaningful contribution to knowledge and practice. Some progress has been made, as discussed above. But we still do not quite understand (or at least we have not fully internalized) fairly basic things about the accrual process. For example, consider the following situation: a mature firm has no growth, and so its assets and liabilities stay roughly the same. For such a firm, can the quality of accruals deteriorate over time? Intuitively, the answer must be yes. But in the current literature (Richardson et al. 2005), the definition of accruals is the change in non-cash assets and liabilities. So, for a firm like this which has no change in non-cash assets and liabilities, the accruals are zero, which means there are no accruals. But that sounds strange then, how can you talk about the properties of something when that something doesn't even exist?! So, what is the answer to this puzzle?

To clarify the logic, let's make the question more specific. For a mature firm with zero growth, how can the quality of accounts receivable change? The answer is that for such a firm the *net* receivable accrual is zero (the change in the Accounts Receivable account is zero for the year) but you still have *gross* receivable accruals during the year. Specifically, the firm collects the old receivables, and originates new receivables. And the point is that the new receivables can have entirely different properties from the old receivables, for example they can be from more marginal customers. So yes, the quality of receivables can go down during the year, even though the net receivable accrual is zero for the year. When you think about this question the right way, the answer is obvious.

What I am trying to say here is that the great paper on the difference between net and gross accruals has not been written yet, while I think there will be a paper on that at some point. It does seem to be a key and consequential difference. To illustrate, let's develop this idea further, and say that we are going to regress accruals on cash flows. This is the most basic regression in this kind of research, with variations of it appearing in countless studies. What kind of accruals should we put on the left-hand side of this regression? And to be clear what we are doing, let's make this more specific, let's say that this is about revenue accruals, and we have only accounts receivable and no deferred revenues. So, that implies that we will be putting the accounts receivable accrual on the left-hand side, while the corresponding cash flows go on the right-hand side, and for revenues that will be cash collections from customers. So, what kind of accruals should we put on the left-hand side? Using the Richardson et al. (2005) definition, it should be the change in accounts receivable because that is the definition of the receivables accrual. However, this answer does not seem quite right. What would make more sense is that we need the accounts receivable to be matched with the cash flows which were collected from these same receivables, which implies that we need some kind of gross accruals on the left-hand side, not net accruals. So, who is putting the gross accruals on the left-hand side for such regressions? Pretty much nobody at this point. The implication is that there needs to be some re-assessment of the very basics of what we do in accrual research. Needless to say, there will be a significant premium attached to the work that can solve such fundamental problems.

Another example of the danger of misunderstandings of the basic properties of accruals is the interpretation of the empirical relation between contemporaneous cash flows and accruals. For example, some studies interpret the high negative correlation between concurrent cash flows and accruals (or equivalently, a high ratio of cash flow to earnings volatility) as indicative of opportunistic earnings smoothing. In addition, Bushman, Lerman, and Zhang (2016) show that the negative correlation between contemporaneous operating cash flows and working capital accruals has declined to just about zero in recent years. These are both fine points, and are well-taken. However, what I'm really concerned about is not so much these studies per se but about a possible misinterpretation and confusion about their results. Even before looking at the empirical results, it would help to be clear that the negative correlation between cash flows and accruals is an *unavoidable* property of accrual accounting, it happens any time the recognition of a cash flow is shifted over time. In fact, this correlation is −100% between properly specified accruals and their associated contemporaneous cash flows (Dichev and Owens, 2020). If you bought Inventory for $200 cash, that is a debit to Inventory of $200 (a positive accrual) and a credit to Cash of $200 (a negative cash flow), a perfect negative correlation of −100%. Of course, things look much messier on the empirical side because in any given period you also have the other side of the Inventory accrual – expensing to COGS which is not related to the Inventory cash flows - and various one-time items and revaluation accruals that weaken the negative association to something less than −100%. But the basic point remains. Having a firm grasp of the unavoidable strong negative correlation between concurrent associated accruals and cash flows helps in the interpretation and calibration of empirical results.

6.4. More attention on standard setting and "what is good accounting?"

Standard setting matters. It sets the tone in financial reporting practices, and whether and how the world sees the value-added of accounting. And to be completely honest, what worries me is that I think standard setting today is going in the wrong direction, for both U.S. GAAP and IFRS (Dichev, 2017). Standard setters espouse a balance sheet orientation of financial reporting, emphasizing the valuation of assets and liabilities, and with little care for the income statement, and the paramount importance of earnings. This balance sheet orientation is at odds with how most companies conduct their operations, and think about value creation. For most companies, assets and liabilities are just the necessary props to ensure the success of operations, and the emphasis is on making various operational bets, essentially advancing expenses to earn revenue and profit. In other words, operations inherently follow an income statement logic for most companies, and the balance sheet orientation of standard setting is at odds with that.

Whether you agree with the above assessment or not, it is probably safe to say that there is relatively little engagement between accounting academia and standard setters today. Standard setters have trouble finding value in the academic literature, and the decisions on standards are rarely driven by research findings. In turn, standard setting-oriented work seems to garner little respect from the research journals, and the research community in general. This situation seems puzzling given the importance of standard setting. The scant engagement of accounting academics in rule-making, and practice in general, also seems at odds with what our sister disciplines do in their fields. For example, economics has a keen interest in policy questions, and there is considerable interaction between practitioners and academics at all levels, including many academics serving in top policy jobs like Chairman of the Federal Reserve and Chairman of the Council of Economic Advisors.

So, what can be done to improve standard setting? This is a subject for a much longer conversation but in a nutshell, I suggest three things. First, we need a clear articulation of the fundamental relation between cash flows and accruals across the financial statements (complemented by disclosure). For example, we should have clear articulation between "Revenue" on the Income Statement, "Accounts Receivable" and "Deferred Revenues" on the Balance Sheet, and "Cash Collections from Customers" on the Statement of Cash Flows. The idea is that we need a clear link and articulation for all major accruals and their corresponding cash flows across the major financial statements. Right now, this articulation is greatly muddled to impossible depending on the item. Second, and partly related to the first point above, we need clear disclosure about the estimates and their realizations for the most important accounting estimates. Current GAAP already requires firms to make Critical Accounting Policies disclosure in their financial reports. And so the idea is to make this disclosure much more specific, where for each critical accounting policy firms present their estimates and realizations for the current period. Such disclosure already exists for some items, e.g., some firms reconcile their beginning and ending warranty liability with their warranty expense and warranty claims paid for the current period. The point is to extend such disclosure to all important accruals. As one immediate benefit, it will be much harder to manage earnings if this information is readily available. Third, we need a clear separation of the results of operating and financing activities since they have quite different functions and implications for firm value.

7. Conclusion

Fifty years of capital markets research in accounting is really not such a long time considering the centuries of research tradition in older fields of science. So, we can be proud of the enormous progress made in this literature, from fairly humble beginnings to the great sophistication today, especially on the technical side. And yet, I feel that we have only scratched the surface, and that there are great opportunities ahead. Ideally, future accounting research will retain its rigor but move closer to practice, including standard setting.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Working capital and financial performance in MENA region

Osama EL-Ansary and Heba Al-Gazzar
Department of Business Administration, Cairo University, Giza, Egypt

Received 23 March 2020
Revised 12 August 2020
Accepted 14 September 2020

Abstract

Purpose – This paper aims to investigate the possible non-linear effect of net working capital (NWC) level on profitability for Middle East and North Africa (MENA) region listed companies. Furthermore, the study tests the possible interactive effect of cash levels on the relationship between NWC and profitability.

Design/methodology/approach – NWC level is the independent variable and profitability is the dependent variable using two proxies, return on assets (ROA) and returns on equity (ROE). Control variables are size, leverage, gross domestic product growth and sales revenue growth. The generalized method of moments was used to analyze the data of 134 consumer-goods listed firms in 12 MENA countries for the period 2013–2019.

Findings – The results demonstrate that NWC levels had a non-linear effect on profitability using ROA as a profitability proxy while results were insignificant using ROE as a profitability proxy. Furthermore, results show the absence of interactive effects between NWC, cash levels and both profitability proxies.

Originality/value – The study fills a gap in the working capital management (WCM) literature by providing new evidence on WCM's non-linear effect of corporate performance in the MENA region emerging markets using the consumer-goods industry sample. The study contributes to the financial managers' working capital optimization efforts in the MENA region by providing evidence on the usefulness of WC optimization efforts in the region from a financial performance point of view. According to the researchers' knowledge, a few studies attempted to investigate this non-linear relationship for neither MENA region countries nor the consumer-goods industry.

Keywords GMM, Working capital management, MENA, Cash holdings, Consumer goods firms

Paper type Research paper

1. Introduction

Many of the emerging markets in the Middle East and North Africa (MENA) region, which comprises 19 developing countries, are still recovering from the 2008 crisis and the region's extreme political instability, according to the World Bank Publications (2017). The markets are yet suffering from slow growth, with fiscal deficits expected to widen and investments expected to decline.

This region's general economic condition has many implications, necessitating effective working capital management (WCM). According to the World Bank Publications (2017), while most countries in the region have equity markets and a sophisticated banking system,

Authors would like to thank Mubasher International Group for providing us access to their financial database "Decypha" for listed firms in the MENA region. www.decypha.com

access to finance by the private sector is limited. Indeed, according to The Organization for Economic Co-operation and Development (OECD) (2008), internal funds represented the main source of funds to firms in the MENA region. The reasons pull back to high-interest rates, high economic uncertainty and higher overall collateral required by banks, which makes short-term funds more accessible and longer-term funding less available. The higher importance of efficient WCM in developing countries is even more vital for production-oriented firms whose current assets (C/A) comprise a large proportion of its total assets such as inventory (Horne and Wachowitz, 1998).

Many studies have investigated the linear effect of efficient WCM on corporate performance. Only recently, Baños-Caballero *et al.* (2014) revealed for the first time the existence of a non-linear relation between working capital and corporate performance, implying the existence of an optimal working capital investment level that can maximize corporate returns. With the daily remarkable effort that financial managers exert to manage and optimize their working capital levels, these results have important practical implications.

Being recently proposed and confirmed by several later studies (Mun and Jang, 2015), a wide literature gap exists in confirming the existence of this effect in different industries and under different market structures. Specifically, to the researchers' knowledge, no study attempted to investigate this non-linear relationship for neither developing countries nor the consumer-goods industry.

This paper aims to fill this gap in the literature by answering the following question: considering a possible non-linear relationship, what is the effect of net working capital rate (NWCR) level on profitability (return on assets (ROA)/returns on equity (ROE))? Furthermore, the study tests the possible interactive effect of cash levels on the relationship between net working capital (NWC) and profitability. To test the validity of the study hypotheses for listed consumer-goods firms in the MENA region for the period 2013 to 2019, the generalized method of moments (GMM) was used.

The paper is divided into seven sections, starting with the introduction and followed by WCM strategies and policies in Section 2 and the literature review in Section 3. In Section 4, hypotheses are developed. Section 5 presents the followed methodology and Section 6 reports the empirical evidence. Section 7 concludes the paper and spotlights practical implications, study limitations and future research.

2. Working capital strategies and policies

WCM is an increasingly vital area in firm finance. In this section, we will shed light on the strategies, concepts, policies and decisions that were introduced in the literature. We found the following five directions in the academic research, namely, working capital investment (WCI) and working capital finance (WCF), conservative and aggressive, maturity matching, speed adjustment for financial crises and cash holding decision and permanent versus seasonal cash flows.

The first direction explains how WC could be managed to finance C/A as a short-term investment WCI, simultaneously, selecting the appropriate current liabilities (C/L) as short-term sources of finance WCF. Achieving the required balance between short-term sources of finance and short-term investments in C/A is a real challenge facing professional financial managers to avoid solvency/deficit and to increase profitability. Besides, achieving wealth maximization for shareholders. Most of the previous studies confirmed the fact that WCM selected policy has an impact on its financial performance (Altaf and Ahmad, 2019; Baños-Caballero *et al.*, 2019).

If the financial manager achieves the balance between allocating investments in C/A and financing WC this decision is known as a WC policy (Altaf and Ahmad, 2019). Successful selection of WCM policy will directly lower/affect the firm's cost, risk, sustainability and increase profitability as pointed out by may authors (Peng and Zhou, 2019; Salehi, Mahdavi, Dari, and Tarighi, 2019; Laghari and Chengang, 2019).

Second, the WCM policy could be conservative or aggressive. Conservative policy focus on allocating large funds in C/A financed by low short-term sources of C/L or aggressive policy where allocating small funds in C/A, which are financed by a large volume of short-term sources of finance, as pointed out by Altaf and Ahmad (2019) and Kayani, De Silva, and Gan (2019). The trade-off between using the conservative or aggressive strategies for WCM may result in a non-linear relationship (inverted U-Shape) between WC finance and firm financial performance as found by Baños-Caballero *et al.* (2012); Mun and Jang (2015), Singhania and Mehta (2017); Altaf and Shah (2017), Laghari and Chengang (2019); Altaf and Ahmad (2019). They reported a concave relation between corporate profits and WCM. The simple definition for the inverted U-Shape (concave) relationship between corporate profits and WCM was explained by Altaf and Ahmad (2019, p. 473) "[. . .] when firms finance working capital with lower levels of short-term debt, firm performance improves while with the higher level of short-term debt used to finance working capital, firm performance decreases."

The third direction emphasizes the maturity structure for C/A and C/L. Many firms in the emerging market do not achieve the appropriate matching between C/A and C/L maturities. WCM theory focused on financing working capital through short-term sources of finance but empirically it is not observed as pointed out by Chauhan (2019).

The fourth direction relates to the speed adjustment of firm WC during a crisis that is very significant to achieve or at least to sustain their performance. Tsuruta (2019, p. 206) examined the effect of the financial crises on WCM and stated that "[. . .] to finance any access working capital, firms borrow from banks and reduce their internal cash both during and outside the period of crisis."

The fifth direction is concerned with the cash holding decision. Mun and Jang (2015) examined the interaction relationship between cash holding and WCM policy impact on a firm's profitability. They found that the corporate's optimal cash level is one of the important factors for profitability. Their results stated that: "[. . .] interactive effects exist among working capital, cash levels and profitability" (Mun and Jang, 2015, p. 1). Thus, for one of our research hypotheses, we used the assumption related to the interaction between WCM, cash Levels and profitability developed by Mun and Jang (2015) to test the inter-relationship between WCM and profitability. Studies extended this direction according to whether a firm faces permeant versus seasonal cash flow. As stated by Ismail (2017), firms' WC needs will increase during special seasons because of high sales and then decline as the collection from clients for accounts receivables (A/R) is more than sales.

3. Literature review

The objective of this section is to cast light on recent research related to the relation between WCM and firm performance. This section is divided into three parts. Part one is devoted to illustrate the relationship between WCM and profitability and part two addresses profitability proxies and finally, part three explains the interrelationship between investment in working capital and cash holding levels.

3.1 Working capital management and profitability

WCM is a vital element of corporate finance that requires considerable time in its day-to-day decisions. According to Ernst and Young (2018) report on working capital practices in the

MENA region, $32.7bn worth of cash opportunity has been identified in 2017. Pirttilä *et al.* (2020) have found that firms operating with efficient WCM policies are usually their supply chains' leaders and are usually considered powerful actors. WCM is important for investors as well. Dhole *et al.* (2019) showed that analysts seem to consider WCM of firms when setting the one year ahead of target price.

WCM is concerned with managing a firm's short-term capital, as per Chiou *et al.* (2006) definition. Short-term capital comprises C/A and C/L that companies use to run their daily business and operations. One measure that managers use to keep track of their working capital levels is the cash conversion cycle (CCC), which mirrors the period amid the corporate cash payments to its suppliers and the time it collects its receivables from customers.

Many studies tested the relationship between working capital and the firm's performance. The results fall into two competing views.

Under one point of view, further investments in working capital are expected to have upside effects on a firm's financial performance especially for firms with a low level of NWC. The rationale is intuitive. According to Blinder and Maccini (1991), Fazzari and Petersen (1993); Corsten and Gruen (2004), holding larger levels of inventories can decrease costs of supply, hedge against input price uncertainty and prevent operational disruptions and loss of business opportunities due to stock-outs. Granting trade credit also positively affects the sales of the firm because it can act as an effective price-cut, serve as a pledge for product quality and nurtures long-term customer relationships (Wilson and Summers, 2002; Brennan *et al.*, 1988; Long *et al.*, 1993).

Another strong explanation for the incentive of firms to hold positive NWC is that it may act as a source of internal funds that secures precautionary liquidity (Fazzari and Petersen, 1993). Furthermore, maintaining positive NWC levels allows a firm to receive a supplier's early payment discounts and enhances the firm's stakeholder relationships (Wilner, 2000; Ng *et al.*, 1999). Pestonji, and Wichitsathian (2019)'s study also revealed a statistically significant positive relationship between working capital investment policy and profitability when they examined a sample of 68 companies listed in the Stock Exchange of Thailand covering the production sector.

Despite all these tempting reasons to raise NWC levels, there are adverse effects on firm value as the working capital level rises beyond a certain point. Many studies have revealed such a negative relationship between a corporation's profitability and working capital levels such as Wang (2002); Jose, Lancaster, and Stevens (1996); García-Teruel and Martinez-Solano (2007); Dong and Su (2010); Baños-Caballero *et al.* (2014). Likewise, applying his study on the real estate and construction sector of UAE, Mehta (2014) found that the longer the CCC, the lesser will be the profitability.

The analogous results root from different intuitive reasons such as that holding inventory stock requires bearing additional costs as warehouse and insurance that increases as inventory levels rise, according to Kim and Chung (1990). Raising working capital levels also entails higher financing and opportunity costs, which, in turn, increases credit risk (Kieschnick *et al.*, 2013). Firms and practitioners are, therefore, aware that increasing working capital levels beyond a certain point put them under higher risk of financial distress and bankruptcy besides locking up more cash (Deloof, 2003).

Recently in literature, combining these potential benefits and costs has produced several studies confirming a non-linear effect of working capital levels on firms' financial performance, with the expectations of a negative relation at a high level of working capital (i.e. overinvestment in NWC) and a positive relation at a low level of working capital (i.e. underinvestment in NWC). Using a sample of small and medium-sized enterprises (SMEs), Baños-Caballero *et al.* (2012) also found a non-monotonic relationship between working capital level and firm profitability.

Baños-Caballero *et al.* (2014) later raised an argument in 2014 that there is an inverted U-shaped relationship between a firm's net trading cycle (a proxy used for WCM) and its performance, measured as the sum of the market value of equity and the book value of debt to the book value of assets. They suggested that a firm should increase investments in working capital to increase the firm's sales and early payment supplier's discounts. This should be limited, however, to a certain point where longer net trading cycles result in lower firm performance. Implications of this new evidence in working capital literature suggest that managers should maintain an optimal level of working capital that balances the tradeoffs and maximizes the firm's performance.

In 2015, Mun and Jang (2015) have criticized Baños-Caballero *et al.* (2014)'s approach in measuring WCM using CCC because it fails to capture the whole picture of WCM by ignoring the role of cash level. They argued that the effect of working capital investments on profitability would differ according to the cash level held by the firm. They also added to their criticism that a firm's value is affected by other aspects, beyond just operational ones, in their WCM measure.

Accordingly, Mun and Jang (2015) tested for non-linearity in the relationship between WCM using the traditional NWC measure and firm's profitability (using operating return on assets (OROA) as a proxy). Their results revealed a significant inverted-U shaped relationship between WCM and profitability, consistent with Baños-Caballero *et al.* (2014). The cash levels showed a significant interactive effect on the relationship between working capital and the firm's profitability only when working capital levels were positive. Similarly, in 2015, Aktas *et al.* (2015) reached similar conclusions for a comprehensive US sample over 30 years.

Evidence in the literature showed that the relationship between working capital and corporate performance is not static. Baños-Caballero *et al.* (2016)'s study reports that working capital requirement financing-performance relation changes during a financial crisis. As he studied a sample of 6,926 non-financial UK SME's for the period from 2004–2013, Afrifa (2016) recorded similar findings. Similarly, Dalci and Ozyapici (2018)'s study reveals a non-linear relationship between working capital and profitability with different leverage levels as a moderating variable. More similar results were reported (Altaf and Ahmad, 2019; Altaf and Shah, 2018).

Literature has extended the testing of this possible nonlinearity in working capital-corporate performance relationship to emerging markets. Altaf and Shah (2017)'s study on 437 non-financial Indian companies confirmed the inverted U-shape relationship between WCM and firm performance. In 2019, Laghari and Chengang (2019)'s study using a large sample of Chinese listed corporations over the period 2005 to 2015, their study revealed a significant reverse U-shaped relationship between WC and corporate profitability. Singhania and Mehta (2017) also found similar results using financial data of listed firms in 11 economies of the Asia Pacific region. Also, despite finding that the relationship between working capital and corporate performance is negative, Wang, Akbar, and Akbar (2020) reported that this relationship is not static across different stages of a firm's life cycle (Laghari and Chengang, 2019).

In his study, Abuzayed (2012) found that the CCC has a positive effect on the firm's profits. This designates that more profitable firms have weaker motives for managing their working capital levels. Moreover, financial markets failed to punish managers for inefficient WCM in emerging markets suggesting that policymakers in emerging markets need to encourage managers and shareholders to care more about managing their working capital through enhancing investors' awareness and improving information transparency.

On the contrary, to examine the impact of WCM on corporate performance and value using a sample of Egyptian firms, Moussa (2018)'s study demonstrated a positively associated with CCC length, failing to achieve optimum efficiency of WCM performance.

3.2 Profitability proxies

Authors in working capital literature used either ROA, OROA and/or ROE as measures of firm profitability. García-Teruel and Martinez-Solano (2007) examined the effects of WCM on profitability. Their sample covered small and medium enterprises in Spain, and they used ROA as a profitability proxy. Wang (2002) on 1,555 Japanese companies and 379 Taiwanese companies for a period from 1985 to 1996, used OROA and pre-tax ROE as operating performance proxies. A similar study context was conducted earlier by Jose *et al.* (1996) using both OROA and pre-tax ROE on a big sample of 2,718 corporations from 1974 to 1993. Besides, Prasad *et al.* (2019) have developed a multiplier of working capital efficiency that directly measures the WCM's profitability and is a product of three elements, namely, a ratio of the sum of trade receivables and inventories to trade payables, the ratio of NWC to net sales and weighted average cost of capital.

Another widely cited study investigating the relationship between the efficiency of WCM and its profitability was published by Shin and Soenen (1998), who investigated 58,985 samples in 8 industries for the period 1975–1994. ROA and the return on sales were used to measure profitability.

Based on these studies, we adopt two measures of profitability. First, because we are interested in the effect of NWCR levels on operating performance, we used net operating ROA as a profitability proxy measured as earnings before interest and taxes (EBIT) divided by total assets.

Second, while ROA measures the efficiency of the firm's management and is of great importance to a manager's performance evaluation, ROE on the other side is of more interest to another stakeholder; that is stockholders. According to Hagel *et al.* (2010), in their Harvard business review article, "most analysts and investors tend to focus on ROE as their primary measure of company performance [. . .], which focuses on return to the shareholders of the company." Although the former authors have preferred ROA as a more accurate financial performance metric, nonetheless, the management of liquidity affects a firm's debt structure because it involves mutually the management of assets and liabilities. Therefore, using both metrics as financial performance proxies allows us to split asset management and financing influences on profitability (Jose *et al.*, 1996).

3.3 Investment in working capital and cash holding levels

Cash is the most liquid, but least profitable asset. The benefits of holding cash go back to 1934 when Keynes (1934) explained the precautionary and transaction motives of holding cash.

Holding cash, however, does come with drawbacks. As Kim *et al.* (1998) stated, liquid assets have low returns and lead to higher taxation. Furthermore, high levels of cash holdings create more agency problems, according to Jensen (1986). Firms, should, therefore, target an optimal cash level that balances both marginal returns and costs of holding cash, as per the tradeoff theory.

Four critical factors explain the variance in corporate cash holdings, according to Bates *et al.* (2009): cash flow volatility, working capital, capital expenditures and R&D expenditures. The researchers examined cash flow uncertainty in American firms throughout the period 1980 up to 2006. Their study revealed that as cash flows become riskier and account receivables are reduced, a firm will tend to hold higher cash levels, supported by a similar conclusion by Campbell and Shiller (2001), Irvine and Pontiff (2008).

The role of cash in the working capital-corporate performance relationship was indirectly evident in a study by Tsuruta (2019) using quarterly firm-level data of listed firms in Japan, who found that working capital adjustments were weaker during the crisis. Furthermore, the negative relationship between excess working capital and corporate performance became significantly higher during crisis times, specifically for large corporations. Nevertheless, evidence point that this crisis-related working capital–firm performance effect does not continue for prolonged periods because to finance any excess working capital, corporations borrow from banks and lessen their cash throughout periods of crisis and beyond.

Generally, small-sized companies tend to hold more cash because of their higher operating and financial risks, relative to their bigger counterparties (Fazzari and Petersen, 1993; Opler, Pinkowitz, Stulz, and Williamson, 1999; Kim *et al.*, 1998). They debate that high cash flow volatility and strong growth opportunities bring firms to hold higher cash levels than their opposites, while bigger firms with higher credit ratings; and therefore, have a better ability to raise capital from debt and equity markets, hold less cash.

According to this review on cash holdings literature, "[. . .] the relationship between a firm's capability to generate cash from operations and the level of actual cash holdings is important to understanding a firm's WCM" (Mun and Jang, 2015, p. 3). Specifically, if a firm can generate cash from operations and/or able to turn working capital to cash smoothly and timely, then one might expect it to hold less cash on hand. A firm holding simultaneously positive NWC and positive cash holding positions imply that working capital is mainly driven to positive values by cash assets rather than non-cash assets (inventories, accounts receivables and accounts payable). This might be the reason for the inability to turn non-cash working capital assets to cash quickly or because of higher business risks. For either reason, the firm incurs opportunity costs, which negatively affect its profitability. While holding positive levels of working capital may have negative effects on a firm's financial performance as hypothesized in the previous section, it can be expected that holding positive cash levels will increase the steepness of the negative relation between positive WC and financial performance.

On the contrary, a firm with a positive NWC level and a negative cash holding level signals the dominance of the non-cash assets in generating positive NWC values. This implies a good ability of a firm to generate internal cash easily, and thus, holding negative cash levels, which are rather invested in accounts receivables, inventory or paying off accounts payable to enhance the performance of its operations. In other words, a firm that aims to increase working capital targets non-cash asset increases rather than cash holdings. One would expect that the negative relationship between NWCR and profitability will be enhanced by holding negative cash levels. Therefore, the researchers propose that the level of cash has an interactive effect on the effect of NWCR on profitability (using ROA and ROE).

A firm, on the other side that holds negative NWCR levels, but a positive cash level might imply insufficient cash generated internally. With the motives of holding cash reviewed earlier, we expect such firms with weak cash-generating abilities to hold positive cash levels. Thus, these firms are likely to increase their NWC levels by rather increasing cash levels than non-cash assets, which imply higher opportunity costs. Consequently, the positive effect of NWCR and profitability is expected to worsen by holding positive cash levels.

In the case of both negative NWCR and cash holding levels, implications are mixed. First, a negative cash holding level might signify a good cash generation capability where firms would rather increase the non-cash assets portion of the working capital to achieve operational benefits than increasing cash levels. Accordingly, the positive relationship between negative NWCR and profitability is expected to improve. If this situation, however, implies a bad cash-generating ability, the probability of the firm to survive is doubtful and should not be considered in the analysis.

4. Hypotheses development

4.1 Net working capital level and profitability

Controversial results on the effect of NWC levels on profitability go back for decades in the literature as presented in the previous section. These competing views about the effect of NWC investments on profitability have produced recent studies suggesting an inverted U-shaped relationship between NWC and firm's profitability such as Baños-Caballero *et al.* (2014); Mun and Jang (2015).

To test this possible non-linear relationship, this paper divided the sample into two groups according to their WCR levels (positive and negative) and hypothesized the following:

H1. "There is a statistically non-linear effect of NWC on profitability."

H2. "If a firm's NWC is positive, there is a statistically negative effect of NWC on profitability."

H3. "If a firm's NWC is negative, there is a statistically positive effect of NWC on profitability."

The independent variable is NWCR measured as the NWC divided by sales to provide a relative measure across different countries and currencies. NWC is the difference between C/A and C/L; both classified into cash and non-cash items.

To measure profitability, the study uses two proxies, one at a time, to explore the effect of NWC on different proxies for profitability, namely, OROA and ROE. OROA measures the effect of NWC levels on operating performance, measured as EBIT divided by total assets. ROE, on the other hand, is of more interest to stockholders. Testing both metrics as profitability proxies allow us to separate asset management and financing influences on profitability (Jose *et al.*, 1996).

4.2 Cash holding level

"The relationship between a firm's capability to generate cash from operations and the level of actual cash holdings is important to understanding a firm's WCM" (Mun and Jang, 2015). Their study showed a significant interactive impact of cash holding levels on the relation between working capital and the firm's profitability only when working capital levels were positive.

To test for the presence of the interaction effect of cash level, this paper further divided the firms into two sub-groups according to their cash holding levels (positive and negative, using a dummy variable for cash levels; (1) for positive and (0) for negative, hypothesizing the following:

H4. "If a firm's NWC is positive, the negative effect of its NWC on profitability will significantly differ based on its cash level (positive or negative)."

H5. "If a firm's NWC is negative, the positive effect of NWC on profitability will significantly differ based on its cash level (positive or negative)."

Cash level is measured using the cash level rate (CASHR) calculated as cash and cash equivalents minus current debts.

5. Methodology

5.1 Samples and data

The sample analyzed covers 134 listed consumer goods corporations in the MENA region from the period 2013 to 2019. A specific industry has been analyzed because the WCM practices differ between industries suggesting the non-homogenous effects of WCM on different corporate performance metrics (Boisjoly *et al.*, 2020). Therefore, our study focuses on a certain sector because of the different practices and norms across different industries (Chauhan, 2019).

The financial data in this paper comes from the annual financial statements on the Decypha database (www.decypha.com). To include the economic cycle effects on working capital investment levels, the researchers gathered the annual gross domestic product (GDP) growth data for the MENA region countries from the World Bank database (www.worldbank.org).

The study follows the industry classification standards of FTSE Russell Industry classification standard (2018). According to FTSE Russell Industry classification standard (2018), the consumer goods industry includes the following super-sectors, namely, automobiles and parts, food and beverages, personal and household goods, which are further divided into sectors and sub-sectors. Table 1 below illustrates the sample details.

5.2 Model specification and methodology

To test *H1* of a possible concave relationship between working capital and firm profitability, we estimate the following quadratic model using two profitability proxies interchangeably, namely, ROA and ROE. Table 2 follows with variables description.

Model (1):

#	Country	No. of listed corporations analyzed	Country's share from total sample "Rounded figures" (%)
1	Egypt	37	27
2	United Arab of Emirates	9	6
3	Morocco	8	5
4	Saudi Arabia	16	12
5	Kuwait	4	3
6	Qatar	4	3
7	Oman	16	12
8	Palestine	6	4
9	Tunisia	14	10
10	Iraq	12	9
11	Bahrain	2	1
12	Jordan	6	4
	Total	134	100%

Notes: According to the World Bank, the MENA region comprises 19 countries. Our sample only covered 12 countries excluding Yemen, Djibouti, Algeria, Iran, Lebanon, Libya and Syria due to data unavailability or firms listed had mixed lines of business besides consumer goods

Table 1. Study sample

Table 2.
Variables description table

Variable	Acronym	Formula	Description and citation
Dependent variable/s			
Return on assets	ROA	Earnings before interest and tax (EBIT) divided by total assets = EBIT/total assets	Following (Jose *et al.*, 1996; Wang, 2002) we apply both ROA and ROE to separate asset management and financing influences on profitability - ROA, used as a profitability proxy, is calculated using EBIT to reflect the net operating profits of the firm and avoid non-homogenous interest and tax rates across countries - Authors who used ROA as a profitability proxy (Wang, 2002; Falope and Ajilore, 2009; Şen *et al.*, 2009; Alavinasab and Davoudi, 2013; Erasmus, 2010; Pirttilä *et al.*, 2020; Singhania and Mehta, 2017; Laghari and Chengang, 2019; Baños-Caballero *et al.*, 2012)
Return on equity	ROE	Net income divided by total shareholders' equity ROE = net income/shareholder's equity	ROE, used as another profitability proxy that reflects a more investor-oriented profitability proxy and reflects firms' financing strategies - Authors who used ROA as a profitability proxy (Wang, 2002; Samiloglu and Akgün, 2016; Sharma and Kumar, 2011; Jose *et al.*, 1996)
Independent variables			
Net working capital rate	NWCR	$NWCR = \frac{\text{Inventories} + \text{Trade Receivables} - \text{Trade Payables}}{\text{Sales}}$	Working capital level neutralized across firms by dividing net working capital by sales (Tsuruta, 2019; Hill *et al.*, 2010; Aktas *et al.*, 2015; Afrifa, 2016)
Control variables			
Firm size	Size	Natural logarithm of total assets	Size is controlled because of the economies of scale concept that directly affect firms' profitability (Laghari and Chengang, 2019; Baños-Caballero *et al.*, 2012; Wang *et al.*, 2020; Moussa, 2019; Şen, *et al.*, 2009)
Leverage	LEV	Total liabilities divided by total assets	Leverage affects working capital management practices and is controlled for in this study (Laghari and Chengang, 2019; Baños-Caballero *et al.*, 2012; Wang *et al.*, 2020; Moussa, 2019)
Sales growth	Growth	Sales growth rate calculated as = $(Sales_{n} - Sales_{n-1})/Sales_{n-1}$	Sales growth is used as a proxy for firm growth that directly affects working capital management practices

(continued)

Variable	Acronym	Formula	Description and citation
			(Laghari and Chengang, 2019; Baños-Caballero *et al.*, 2012; Wang *et al.*, 2020; Afrifa, 2016; Hill *et al.*, 2010)
Cash level	Cash	(Cash and cash equivalents)/sales	To test whether cash levels play a moderating role in the relationship between working capital and profitability, cash level was used as a dummy variable and an interaction term "cash level * NWCR" is added to the model For authors who used cash as a control variable (Afrifa, 2016; Laghari and Chengang, 2019)
Economic growth	GDP	Real GDP growth rate calculated as = $(GDP_{n} - GDP_{n-1})/GDP_{n-1}$	Because this study applies cross-country analysis, it controls for different gross domestic growth rates and different inflation levels According to Baños-Caballero *et al.* (2019), the value of net working capital varies across countries and that it depends on both investor protection and a country's financial and economic development (Wang *et al.*, 2020; Altaf and Shah, 2018; Tsuruta, 2019; Moussa, 2019)

Table 2.

$$\text{Profitability} = \beta_0 + \beta_1{*}ROA/ROE_{i,t-1} + \beta_2{*}\text{NWCR}_{i,t} + \beta_3{*}NWCR^2_{i,t} + \beta_4{*}Size_{i,t} + \beta_5{*}\text{GROWTH}_{i,t} + \beta_6{*}\text{LEV}_{i,t} + \beta_7{*}\text{GDP}_{kt} + a_i + \varepsilon_{i,t}$$

where:

ROA_{it}: Operating Return on Assets using EBIT as a proxy for operating income for companies i at time t.
$ROA_{i,t-1}$: ROA one-year lag.
ROE_{it}: Return on Equity for firm i at time t.
$ROE_{i,t-1}$: ROE one-year lag.
β_0: Constant.
$NWCR_{i,t}$: Net Working Capital divided by Sales for firm i at time t.
$NWCR^2_{i,t}$: Net Working Capital divided by Sales all squared for firm i at time t.
$Size_{i,t}$: The natural logarithm of total assets for firm i at time t.
$\text{GROWTH}_{i,t}$: Sales growth rate for company i at time t.
$\text{LEV}_{i,t}$: Leverage as the ratio of total liabilities to total assets for firm i at time t.
GDP_t: Gross domestic product growth rate for country k at time t.
$\varepsilon_{i,t}$: Error term.
i: 134 Company in 12 MENA region countries (Consumer Goods Industry).
t: From 2013 to 2019.
k: 12 countries in the MENA region.

To further test the linear relationship between working capital and profitability "*H2* and *H3*," we estimate the following linear model:

Model (2):

$$\text{Profitability} = \beta_0 + \beta_1{*}OROA/ROE_{i,\ t-1} + \beta_2{*}\text{NWCR}_{i,t} + \beta_3{*}Size_{i,t} + \beta_4{*}\text{GROWTH}_{i,t} + \beta_5{*}\text{LEV}_{i,t} + \beta_6{*}\text{GDP}_t + a_i + \varepsilon_{i,t}$$

Upon testing the possible non-linear relationship between working capital and profitability, suggesting a possible optimal working capital level, we attempt to explore the impact of cash level on this optimal level. We estimate the following model to test this possible interaction effect as follows testing *H4* and *H5*:

Model (3):

$$\text{Profitability} = \beta_0 + \beta_1{*}NWCR_{i,\ t} + \beta_2{*}\text{CASH}_{i,t}(\text{Dummy}) + \beta_3{*}\left[\text{N}WCR_{i,t}{*}\text{CASH}_{i,t}(\text{Dummy})\right] + \beta_4{*}\text{GROWTH}_{i,t} + \beta_5{*}\text{Size}_{i,t} + \beta_6{*}\text{LEV}_{i,t} + \beta_7{*}GDP_t + a_i + \varepsilon_{i,t}$$

To test whether the independent variables can explain the profitability's variance significantly, this study applied regression analysis. Diagnostic tests were applied to test normality, multi-collinearity, heteroskedasticity, autocorrelation and heterogeneity to confirm whether the ordinary least squares (OLS) assumptions have been met or not.

Normality was tested using Jarque-Bera, which confirmed that none of the variables is distributed normally, but because of the large sample of the study (Field, 2009, p. 134) and the use of the GMM as a statistical tool of regression analysis, this will not cause major problems.

Besides, we used the variance inflation factor (VIF) to test the absence of multi-collinearity in our independent variables. A common cutoff value/point is a tolerance value of 0.10, which corresponds to a VIF of 10. As the largest VIF value was 1.8, we conclude the absence of multi-collinearity if the value is less than 10 as stated by Sekaran and Bougie (2009, p. 316).

The Hausman test was conducted to detect the endogeneity of unobserved errors and consequently select among fixed-effects and random-effects models. Because the data is unbalanced, we favored a random-effects model over a fixed-effects model as per Bell and Jones (2015) because it is more capable of controlling unobserved heterogeneity, and, hence, mitigate the risk of attaining inclined results stemming from this heterogeneity (Hsiao, 1985).

With these diagnostic tests' results, it is evident that the OLS assumptions are not met. One of the effective approaches to solve autocorrelation and heterogeneity is using a panel data methodology, specifically; the research's models were estimated using the GMM estimator depend on Arellano and Bond (1991). This methodology offers several benefits. According to Himmelberg *et al.* (1999), firms are heterogeneous and it is almost unavoidable to find characteristics that are difficult to measure or obtain and that could affect their value.

The dynamic panel data methodology allows us to control for unobservable heterogeneity (Hsiao, 1985). Besides, it solves the problem of possible endogeneity by using a lagged regressor as an instrument to avoid endogeneity issues (Arellano and Bond, 1991). In our models, ROA and ROE were lagged twice and used as instruments for differenced variables. Therefore, the (GMM) using random effects was used to test for the study's hypotheses.

5.3 Descriptive statistics

Table 3 presents descriptive statistics for the variables under study, using several NWCR sample classifications.

Using the overall study sample, the mean of ROA was 3.5% and ROE was 8%. These figures differed substantially when the sample was divided into positive and negative NWCR. ROA mean was 4% under the positive NWCR sample, and only averaged 1.9% under the negative NWCR sample. ROE was also 6% and 1.7% under positive and negative NWCR samples, respectively.

With an average NWCR of approximately 30% across the overall study sample, the table displays an NWCR mean of 38.3% under the positive NWCR sample and scores a negative 25.6% rate under the negative NWCR sample. Firms within the negative NWCR sample had a bigger size value on average than firms in the positive NWCR sample.

It can also be noticed that larger firms had higher leverage than smaller ones across all sample groups. This conclusion matches literature that smaller firms face higher financing constraints, and therefore, hold more cash than their larger counterparties (Fazzari and Petersen, 1993; Kim *et al.*, 1998; Opler *et al.*, 1999). Practically, this result confirms the fact that a large firm's ability to source external funds and loans is easier than small firms.

Table 4 Follows and displays the Pearson correlation matrix among the variables and supports our previous section's VIF diagnostic test, confirming the absence of multi-collinearity.

6. Empirical evidence

6.1 Working capital effects on profitability

The objective of this section is to cast light on data analysis and testing research hypotheses.

Table 4. Pearson correlation matrix

Table 4 below refers to the GMM regression analysis results to test the relationship between working capital and profitability using Models (1) and (2).

To conclude a concave relation between working capital and profitability, we expect to observe a statistically significant positive *NWCR* coefficient and a negative $NWCR^2$ coefficient in the quadratic Model (1). Under ROA, the results are as expected and *H1* is accepted, implying the presence of a non-linear relationship between working capital and ROA. This result is consistent with the literature (Baños-Caballero *et al.*, 2014; Afrifa, 2016; Mun and Jang, 2015; Singhania and Mehta, 2017; Altaf and Shah, 2017; Laghari and Chengang, 2019; Wang *et al.*, 2020) suggesting the possibility of working capital level optimization.

Conversely, using ROE as a profitability proxy, *H1* was rejected. While many studies tested the linear relationship between ROE and working capital (Jose *et al.*, 1996; Wang, 2002; Sharma and Kumar, 2011; Samiloglu and Akgün, 2016), none to our knowledge has tested the possible quadratic relationship between working capital and ROE.

The reason for ROE model insignificance could be interpreted as MENA region financial managers focus on profit maximization objective to empower their success on the account of achieving wealth maximization when they practice and select their WCM policies and decisions. This strategy will create a serious problem for shareholders and may affect their shares prices in the stock exchange as all the sample firms are listed.

To further investigate the breakdown of these quadratic model results, Model (2) is estimated to examine the linear relationship between working capital and the different profitability proxies using a positive and negative NWCR sample classification (*H2* and *H3*).

H2 states that if a firm's NWCR is positive, there is a statistically negative effect of NWCR on profitability. As shown in the table, *H2* is accepted with a significant negative NWCR coefficient with ROA (−0.02835) and ROE (−0.07012). These results confirm one side of the literature that resulted in a significantly negative relationship between WCM and profitability (Wang, 2002; García-Teruel and Martinez-Solano, 2007; Dong and Su, 2010).

On the other hand, *H3* expects that if a firm's NWCR is negative, its WC will have a positive effect on profitability, is accepted using ROA as a proxy, with a significant positive NWCR coefficient of (0.141723). This result is consistent with many studies in the literature

(Corsten and Gruen, 2004; Fazzari and Petersen, 1993; Blinder and Maccini, 1991). In contrast, the same hypothesis using ROE is rejected due to an insignificant positive coefficient of NWCR. For more comprehensive literature review results regarding the sign direction (+ or −) of the relationship between WCM components and firm performance (Kayani *et al.*, 2019, Table 3, page 356).

This linear Model (2) breaks down the quadratic results, supporting our earlier findings. ROA is found to have an inverted U-shaped relationship with working capital, while ROE only had a significant negative relationship with working capital, and thus, confirming our earlier rejection of a quadratic ROE-NWCR relationship (Table 5).

6.2 Interaction effects of working capital and cash level in the generalized method of moments model

Researchers such as Baños-Caballero *et al.* (2014) and Hill *et al.* (2010) pinpointed that the level of cash flow available will result in more investments in working capital. Furthermore, a study by Fazzari and Petersen (1993) showed that working capital investments are cashflow-sensitive. Thus, this section investigates the possible influence of cash flow availability measured by CASH on the relationship between NWCR and profitability.

To test whether a firm's cash level (cash level) has an interactive effect on the relationship between NWCR and profitability, an interaction term (cash level * NWCR) is added to the GMM model. The (cash level) variable is dummy: (1) for cash levels above sector median and (0) for below sector median levels. Table 6 below illustrates the results of these hypotheses (*H4* and *H5*) using the Model (3).

To confirm a significant moderating effect of cash level on the relationship between working capital and profitability, we expect to find a statistically significant interaction term as explained previously. Using both profitability proxies, ROA and ROE, the interaction term coefficients in both models were insignificant.

This result partly agreed with Mun and Jang (2015)'s results as they found a significant moderating effect for cash levels on the relationship between working capital and profitability, only with firms of positive working capital levels. More specifically, they found that when firms have positive working capital levels, and thus, a negative relationship with profitability, the severity of this negative relationship increases when these firms hold positive cash levels because of the increased opportunity costs of holding cash. They did not find this interaction cash effect when firms held negative working capital levels. Accordingly, our results do not suggest that cash plays any moderating role in the working capital-profitability relationship. This result may direct the attention of financial managers in the MENA region to plan a short and medium WCM policy, cash budget, cash inflow and cash outflow and to provide cash at the appropriate time to achieve the interaction relationship between cash and performance. According to Salehi *et al.* (2019), financial managers should pay more attention to keep cash to finance and control WC to achieve profitability and sustainability of their firm's operations.

Contrary as well to our results, another study conducted by Afrifa (2016) indicated a significant cash flow effect on the relationship between NWC and corporate performance that turns from a strong inverted U-shaped relationship in the absence of cash flow to a convex relationship when cash flow is introduced. Their results suggest that managers should look at their firms' cash flow when determining the appropriate investment to be made in working capital, to improve performance.

Table 6. Interaction effect of NWCR with cash level in the GMM model using ROA/ ROE as the dependent variable testing *H4 and H5*

7. Conclusions

7.1 Summary and discussion

This research aims at first to test the effect of working capital levels on different financial performance measures. Specifically, it uses ROA and ROE as two proxies of profitability, trying to explore the possibility of a non-linear relationship between NWCR and the firm's profitability. In this context and using a sample of 134 listed firms in the MENA region emerging markets, our quadratic model GMM model reported different effects of NWCR on both ROA and ROE. The results showed a significant concave relationship between NWCR and ROA, suggesting the presence of an optimal point to maximize ROA. This finding is consistent with Baños-Caballero *et al.'s* (2014)'s work, as well as Mun and Jang (2015) results; which point out to the presence of a non-linear effect of WC levels on firm value and performance, suggesting an optimal WC level. Moreover, the GMM models allowed us to control potential endogeneity and provide the most robust results. This evidence was not present using ROE.

To further investigate the relationship between NWCR and the profitability proxies, the overall sample was partitioned according to positive and negative NCWR levels. Using a linear model, the results confirmed our earlier results. More specifically, when the positive NWCR sample was used, a significant negative effect of NWCR on ROA was present. One perceptible finding using ROA, as our profitability measure, is that the coefficient's magnitudes of NWCR in the negative NWCR sample are greater than those in the positive NWCR group. This evidence suggests that WC enhanced corporate profits significantly faster for the negative NWCR group than its worsened profits for the opposite sample. When using the negative NWC sample, however, a significant negative relationship was evident between positive NWCR and ROE, implying a linear rather than non-linear relationship.

The study was extended to explore the interactive role of cash level (positive and negative) on the previously hypothesized relationships. Model 3 was used to test this interaction effect of NWCR and CASH in the GMM model. With an insignificant interaction term [$\boldsymbol{NWCR_{i,t}} * \boldsymbol{CASH_{i,t}}$ (Dummy)], the study concluded that the cash level did not significantly affect the relationship between NWCR and firm profitability.

7.2 Implications

7.2.1 Theoretical implications. This study provides important implications for working capital literature and the roots of cash into this literature, shedding light on the emerging MENA region markets. First, the working capital-corporate performance setting has been heavily tested in the literature. According to our knowledge, prior to Baños-Caballero *et al.* (2014)'s original paradigm of testing the non-linear functional form of working capital and corporate performance, all studies assumed a linear functional form of the working capital-corporate performance relationship and made conclusions accordingly. Baños-Caballero *et al.'s* (2014)'s work has been re-tested using samples from developed markets and a few emerging markets. This study's originality stems from testing this non-linear functional form in the emerging MENA region listed firms that, according to our knowledge, has not been investigated previously. An added layer of academic value is achieved as we target a certain sector, namely, the consumer-goods sector, which controls for industry differences and gives a deeper understanding of the working capital effect on corporate performance. This study enhances the working capital investment understanding by using a quadratic model to test the working capital-corporate performance's non-linear relationship.

Second, according to Hill *et al.* (2010) and Baños-Caballero *et al.* (2014), working capital investments are partially driven by cash flow availability, stemming from Fazzari and Petersen (1993)'s study, which indicated that investment in working capital is sensitive to cash flow.

This study addresses this line of research by attempting to investigate the interactive effect of cash level on the relationship between NWC and corporate financial performance, which has been rarely tested in developing markets literature and none was found applied to emerging markets.

Third, this study incorporates two profitability proxies and provides comparative results as to the relationship between working capital and profitability. Unlike published studies, this study used ROA and ROE, reflecting management and investor perspectives, respectively. Our results revealed the different effect working capital has on different profitability measures.

7.2.2 Practical implications. From a practical point of view, this study provides evidence on the existence of an optimal level of working capital that managers need to maintain to maximize operating ROA. This non-monotonic WCM-corporate performance relationship, which happens because of investments in working capital necessitates some proper policy implications by managers to preserve the optimum level of working capital by balancing costs and benefits in an efficient way that maximizes corporate performance.

On a comparative attempt, the study did not find working capital optimization efforts useful if managers attempt to maximize ROE. The study provides evidence of a significant positive linear relationship between ROE and working capital implying that ROE can be maximized by implementing a conservative working capital approach. Investors should carefully and actively evaluate companies' policies regarding working capital before investing to make sure that management is achieving not only profit maximization but also, wealth maximization.

In addition, the research shows that cash flow availability did not have an interactive effect on the relationship between working capital and profitability proxies. This result is opposite to studies applied to developed countries. This suggests that cash levels in developing countries do not reflect the constraints versus availability of financial resources, and thus, does not affect working capital practices and should not affect managers' attempt to maximize ROA. On the other hand, financial managers should concentrate on achieving wealth maximization when selecting their WCM strategies and policies.

7.3 Study limitations and further research

Even though this study contributes toward a better understanding of WCM for consumer goods firms in emerging markets, it unavoidably has some limitations. First, findings may not apply to other industries or similar industries in more developed countries. Second, management practices may differ across countries. Third, although the study sample is based on the Financial Times Stock Exchange (FTSE) Russell industry classification standards, the consumer goods industry inescapably includes many sub-sectors that may not be completely homogenous in their WCM practices, which might affect results.

Thus, it is recommended for future research to test the hypotheses based on country-by-country analysis or in different contexts such as other industries, longer periods; comparing results before and after political disorder or by categorizing MENA countries into more and less developed or by income levels to control for country variances. The inclusion of more firms and country-specific variables in the model could reveal different empirical results and provide a deeper understanding of the relationship between working capital and the firm's profitability.

Besides, it is recommended to research, study and compare the relationship between WCM and profitability for a selected number of seasonal cash flow firms versus a sample of permeant cash flow firms in emerging countries.

Furthermore, according to Kayani *et al.* (2019) 's a systematic literature review on WCM, future research needs to investigate behavioral aspects, qualitative studies, survey studies and systematic theory development when studying WCM (Singh and Kumar, 2014). More attention should be given for investigating the impact of WC on firm value and share market prices to achieve the shareholders' wealth maximization objective.

The international financial crisis and non-financial substantial information have a critical significant effect on WCM practices and short-term cash flow for many emerging capital markets for both listed and unlisted corporations. The current internal financial environment is very volatile and given these circumstances, firms may not be able to fulfill their short-term obligations. Kayani *et al.* (2019) stated that although the world economy faced a liquidity shortage after the financial Tsunami in 2008, little academic attention was given to WCM.

Furthermore, the same phenomena exist now with Covid-19 (CORONA virus), therefore, more research should be directed toward the WCM speed adjustment/recovery during financial crises or eras of pandemics.

Moreover, researching WCM-specialized corporations worldwide that help firms in managing their working capital in new and innovative ways such as factoring, forfeiting, A/R collection and even securitization for medium-term loans or notes might provide valuable insights to the literature.

New variables should also be added to the WCM-corporate performance model such as liquidity risk, which is neglected by most researchers. More research could also be guided toward the management of working capital using the maturity weighted assets and liabilities management gap (duration gap) models between C/A and C/L or weighted by the cost of finance to achieve the required balance between WCF and WCI.

A B S T R A C T

This study investigates the influence of related party transactions (RPTs) on firm value. Further, it examines whether a firm's corporate social responsibility (CSR) reporting reflects its corporate values and ethical concerns, therefore mitigating the value-destroying effects of RPTs. Based on 274 observations from publicly listed firms in Indonesia, our results show that RPTs (i.e., related party sales) are negatively related to firm value. Further, we find that in the presence of better CSR reporting, the relationship between RPTs and firm value becomes more positive. This is in line with the view that CSR reporting, which reflects firms' ethical concerns, may serve as a mechanism against managers' opportunism. However, we find that related party payables have a positive relationship with firm value. Further investigation reveals that, although certain RPTs show a short-term, value-enhancing effect, these transactions seem to result in subsequent tunneling activities, suggesting managerial opportunism in the long term.

1. Introduction

Transparency is an important topic in areas such as management, finance and public relations, and it is essential to enhancing stakeholder trust in a firm (Hultman and Axelsson, 2007; Albu and Flyverbom, 2016; Schnackenberg and Tomlinson, 2016). The disclosure of information is particularly important to minimize information asymmetry, to meet the information needs of external stakeholders and to develop trust. Armitage and Marston (2008) find that managers are motivated to provide greater voluntary disclosure transparency because they want to ensure firms' reputation for openness and shareholders' confidence, which may

result in a higher share price or other commercial benefits. Nevertheless, as firms in many Asian countries are generally characterized by a highly concentrated ownership structure (OECD, 2017) and with concern regarding agency conflict shifting toward the conflict of interest between majority and minority shareholders (Shleifer and Vishny, 1997), insiders of highly concentrated firms (i.e., managers or directors and controlling owners) with better bargaining positions and better access to information have the ability and power to expropriate minority shareholders' interests. One method for such expropriation is related party transactions (hereinafter, "RPTs").

There are two opposing viewpoints regarding RPTs. The first view considers RPTs as potentially opportunistic as they may be used by insiders to maximize self-serving interests at the expense of other shareholders (Gordon et al., 2004; Cheung et al., 2006; Kohlbeck and Mayhew, 2010). However, the second view considers RPTs as potentially efficient as they may provide benefits to firms through a simplified negotiation process, lower transaction costs (Gordon et al., 2004), strategic partnership, risk sharing and the facilitation of contracts (Kohlbeck and Mayhew, 2010).

Some prior studies suggest that firms operating under better ethical concerns, as reflected by their corporate social responsibility (CSR), tend to have less opportunistic behavior (e.g., Garriga and Melé, 2004; Kim et al., 2012; Scholtens and Kang, 2013). Nevertheless, whereas Kim et al. (2012) find that firms that are considered to be socially responsible tend to be more transparent, to have more reliable financial reporting and to be less likely to manipulate reported earnings, another view is that firms may use CSR reporting to conceal corporate misconduct based on opportunistic incentives (Muttakin et al., 2015). Accordingly, using a sample of 274 observations from firms listed in Indonesia, this study investigates whether RPTs enable manager opportunism or efficiency and whether CSR reporting mitigates opportunistic or value-destroying RPTs.

Studies suggest that RPTs in Indonesia are potentially abusive and may lead to the expropriation of wealth by controlling shareholders (Utama and Utama, 2009; Sari and Baridwan, 2014). In addition, Indonesian firms are characterized by high ownership concentration (La Porta et al., 1998; Carney and Child, 2013; Utama et al., 2017). Therefore, conflicts of interest between majority and minority shareholders are more likely to arise. Further, investor protection in Indonesia is still relatively weak compared with other countries (La Porta et al., 2006; Barokah, 2013). Although OJK, then BAPEPAM-LK, has tightened the rules to mitigate opportunistic RPTs, it cannot truly cover all such transactions (Utama et al., 2017).[1] Rule number IX.E. I excludes the obligation to disclose RPTs in relation to a firm's main business activities. However, prior studies argue that such transactions are potentially abusive and thus require more transparency for users of financial statements (Cheung et al., 2006, 2009).

Our findings indicate that concerns about RPTs being both value destroying and value enhancing are warranted. Specifically, this study finds that related party sales are negatively related to firm value. This implies that because the fairness of RPT prices may be doubtful, the market may perceive related party sales as opportunistic and less credible than other sales. However, in the presence of more CSR reporting, the relationship between related party sales and firm value becomes more positive. This finding indicates that ethical concerns may drive firms to be less opportunistic and that CSR reporting reflects firm's incentives to be trustworthy and ethical. Moreover, the relationship between related party payables and firm value is positive, suggesting that the market perceives related party payables as beneficial to listed firms. Interestingly, although these transactions show a short-term, value-enhancing effect, they seem to result in subsequent tunneling activities.

This study makes a number of contributions. First, although CSR has received public attention worldwide, there are relatively few empirical studies on CSR in the context of developing countries, such as Indonesia. This study provides evidence regarding whether RPTs in Indonesia are opportunistic or efficient. Second, this study provides evidence regarding whether ethical concerns drive firms to engage in value-enhancing RPTs instead of opportunistic RPTs. Third, this study sheds light on how CSR reporting affects other corporate behavior besides earnings management and financial performance, namely RPTs. Fourth, this study may be useful to current and potential investors making investment decisions. In particular, as the results confirm the view that firms with more CSR reporting are less likely to behave opportunistically, investors can be assured that resources provided to such firms will be managed efficiently. Lastly, in light of CSR reporting,

[1] BAPEPAM-LK, *Otoritas Jasa Keuangan (OJK),* is the regulator of Indonesia's capital market.

the findings of this study may help regulators and policymakers better understand firms' business practices and the motives for using RPTs and CSR reporting.

The remainder of this paper is organized as follows: Section 2 presents a literature review and the research hypotheses. Section 3 discusses the study's research design. Section 4 presents and discusses the results. Section 5 provides additional analysis on the potential occurrence of subsequent tunneling. Section 6 summarizes the key findings and provides conclusions.

2. Literature review and hypotheses

There are two alternative viewpoints about RPTs: The first considers them to be abusive (opportunistic) transactions, whereas the second view considers them to be efficient (Gordon et al., 2004). Kohlbeck and Mayhew (2017) suggest that RPTs contain potential self-dealing between directors, material owners, officers and investors. Several studies support this view and suggest that as RPTs can be an indicator of agency problems, investors consider them to be opportunistic (e.g., Jian and Wong, 2004; Cheung et al., 2006; Kohlbeck and Mayhew 2010). As insiders of highly concentrated firms, such as managers, directors and controlling owners, have better access to information, they are in a better bargaining position than outsiders, such as non-controlling (minority) shareholders and corporate creditors. Consequently, expropriation by insiders against outsiders' interests are more likely to occur. In such a setting, La Porta et al. (1999, 471) argue that controlling owners tend to have more power to expropriate minority shareholders' interests.

Several other studies, however, argue that RPTs can be beneficial as they may result in saving transaction costs and improving a firm's resource utilization (Chang and Hon, 2000; Chen et al., 2009; Chien and Hsu, 2010). Accordingly, RPTs do not necessarily represent transactions based on fraudulent or deceptive purposes. Instead, RPTs may represent ordinary trade and business activities (Wong et al., 2015). Studies indicate that socially responsible firms tend to be more trustworthy and are more likely to engage in ethical operating decisions. Kim et al. (2012) and Scholtens and Kang (2013) find that socially responsible firms are less likely to engage in earnings management. Similarly, Bénabou and Tirole (2010) argue that CSR can reduce the likelihood of short-term opportunistic behavior by managers. Gao et al. (2014) contend that executives of socially responsible firms are less likely to engage in trading prior to news announcements and profit significantly less from insider trading. Consequently, it is expected that, on the basis of ethics, firms that are perceived as socially responsible are less likely to engage in opportunistic behavior such as value-destroying RPTs; although studies also suggest that firms may be presenting socially responsible behavior to shift stakeholders' focus (Salewski and Zülch, 2014; Muttakin et al., 2015).

Related party sales are undertaken to improve resource allocation efficiency (Wong et al., 2015). However, as the prices charged in related party sales transactions may be unfair compared with industry average prices (Kang, et al., 2014, 277), expropriation may occur. Therefore, RPTs allow shifting earnings between firms, particularly from listed firms to their related parties (Cheung et al., 2006). Several studies have explored the relationship between related party sales and market reactions and contend that the market responds less positively to related party sales transactions (e.g., Jian and Wong, 2004; Cheung et al., 2009). Specifically, in the Chinese context, Aharony et al. (2010) find an association between tunneling in the post-IPO period and upward earnings management through abnormal related party sales in the pre-IPO period. Further, although there may be indications that related party purchases may be conducted at prices higher than independent transactions, studies argue the value-enhancing effect of related party purchases. Chen et al. (2009) argue that RPTs may lower transaction costs, which may in turn improve operational performance and maximize profit. In the same way, Tambunan et al., (2017) provide evidence of the value-enhancing effect of related party purchases, although only in the short term. Accordingly, the following hypotheses are proposed:

H1a. Related party sales negatively influence firm value.

H1b. Related party purchases positively influence firm value.

Prior studies by Jiang et al. (2010) and Tambunan et al. (2017) argue that controlling shareholders may expropriate through related party receivables transactions as they may affect a firm's productive assets and firm value negatively. Stated differently, transactions that involve the payment of cash to related parties (in-

Please cite this article in press as: Hendratama, T.D., Barokah, Z. Related party transactions and firm value: The moderating role of corporate social responsibility reporting. China Journal of Accounting Research (2020), https://doi.org/10.1016/j.cjar.2020.04.002

cluding loans and cash assistance) are likely to result in the expropriation of minority shareholders' interests (Cheung et al., 2006). Hence, it is expected that the higher the related party receivables, the worse the firm value. In contrast, cash assistance or loans received from listed firms from related parties are likely to benefit non-controlling shareholders (Cheung et al., 2006, 358). Unsurprisingly, listed firms that are in severe financial difficulty generally receive cash assistance from related parties. Accordingly, we test the following hypotheses:

H1c. Related party receivables negatively influence firm value.

H1d. Related party payables positively influence firm value.

This study further investigates whether CSR reporting, as the reflection of a company's ethical concerns, can explain the negative relationship between a firm's CSR and corporate opportunistic behavior. As pointed out by Kim et al. (2012) and Scholtens and Kang (2013), a firm's CSR generally has an inverse relation to its earnings management. Although this study focuses on the ethical implications of CSR, other motivations might also explain a negative relation between CSR and opportunistic behaviors. Several studies (Verschoor, 2005; Linthicum et al., 2010; Choi and Moon, 2016) argue that as social responsibility may provide positive signals regarding a firm's reputation, firms that value their reputation want to protect it, and therefore, they avoid socially unacceptable activities that may potentially damage their reputation.

In contrast, although ethical and reputational motivations for CSR may explain a negative association between CSR and corporate opportunistic behaviors, other studies argue the opposite. For example, Prior et al. (2008) argue that firms may use CSR to overshadow their value-destroying practices. Similarly, Muttakin et al. (2015) contend that CSR reporting may be used to divert stakeholders' attention and reduce the likelihood of opportunistic practices being scrutinized. Accordingly, if firms engage in CSR reporting in the context of a moral imperative, firms may be less likely to engage in value-destroying (opportunistic) RPTs and more likely to engage in value-enhancing (efficient) RPTs. Nevertheless, if firms engage in CSR reporting to disguise value-destroying practices as a means to pursue self-interest, then firms are likely to engage in value-destroying RPTs. Thus, this study proposes the following hypotheses:

H2a. CSR reporting moderates the relationship between related party sales and firm value.

H2b. CSR reporting moderates the relationship between related party purchases and firm value.

H2c. CSR reporting moderates the relationship between related party receivables and firm value.

H2d. CSR reporting moderates the relationship between related party payables and firm value.

3. Research design

We tested the hypotheses by using multiple regression analysis. The required data are collected from the Indonesia Stock Exchange (IDX) website and BvD Osiris database. Data on RPTs and CSR are hand-collected from annual reports.

3.1. Sample selection

This study includes firms listed on the IDX in 2014 and 2015 because the first phase of the IFRS convergence process in Indonesia was completed in 2012, and the second phase was completed in 2015.[2] This

[2] The first phase of the IFRS convergence process in Indonesia was completed in 2012; in this phase the Financial Accounting Standards Board (i.e., DSAK) endorsed 35 financial accounting standards (PSAKs) adopted from IFRS, including PSAK 7 Related Party Disclosures (Maradona and Chand, 2018; Ikatan Akuntan Indonesia, 2012). PSAK 7 was then adjusted in 2014 and amended in 2016 (effective January 1, 2016). Based on the timeframe of adjustment and amendment to PSAK 7 Related Party Disclosures, we choose 2014–2015 to have a consistent applicable standard on related party disclosures (i.e., the period before the standard was amended) (Ikatan Akuntan Indonesia, 2015).

Please cite this article in press as: Hendratama, T.D., Barokah, Z. Related party transactions and firm value: The moderating role of corporate social responsibility reporting. China Journal of Accounting Research (2020), https://doi.org/10.1016/j.cjar.2020.04.002

progress is essential to enhance the quality of Indonesian accounting standards and to convince external stakeholders of the quality of the financial reporting practices of Indonesian firms. The study sampling method includes the following criteria: (1) the firm must issue an annual report; (2) it must not be part of the financial industry; (3) its accounting cycle must end on December 31; (4) it must not have negative book value of equity; (5) it must engage in RPTs; and (6) it must disclose social responsibility activities.

3.2. Variables and research models

The independent variables include four types of RPTs. Following previous studies (Cheung et al., 2006, 2009; Chen et al., 2009), this study uses related party sales (*RP_Sales*), purchases (*RP_Purchases*), receivables (*RP_Rec*) and payables (*RP_Pay*). Each type of RPT is measured by the total of transactions (i.e., sales, purchases, receivables, and payables) scaled by total assets. Firm value is measured by Tobin's q and PBV. Subramanyam (2014, 628) and Ahmad and Jusoh (2014, 480) contend that accounting-based valuation methods are more likely to contain management manipulations and distortions as personal goals and interests may depend on the reported accounting data. Therefore, market-based measures are considered to be superior. CSR reporting indices are gathered from content analysis using the checklist proposed by Gunawan et al., (2009) with eight themes: environment, energy, human resources, community involvement, products, sustainability, external relations and others. Each category is elaborated into a few items with 45 disclosure items in total, which are scored for both quantity and quality of CSR reporting.

Several control variables commonly found in the literature are included in the analysis. This study includes firm age, size, leverage, profitability and RPT disclosure as determinants of firm value and controls for industry and year fixed effects. The regression equations are described as follows:

$$\begin{aligned} FValue_{i,t+1} = {} & \beta_0 + \beta_1 RP\_Sales_{i,t} + \beta_2 RP\_Purchases_{i,t} + \beta_3 RP\_Rec_{i,t} + \beta_4 RP\_Pay_{i,t} + \beta_5 FAge_{i,t} \\ & + \beta_6 FSize_{i,t} + \beta_7 Lev_{i,t} + \beta_8 ROA_{i,t} + \beta_9 RPD_{i,t} + \beta_{10-16} Ind_{i,t} + \beta_{17} Year_{i,t} \\ & + \varepsilon \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \end{aligned} \tag{1}$$

$$\begin{aligned} FValue_{i,t+1} = {} & \beta_0 + \beta_1 RP\_Sales_{i,t} + \beta_2 RP\_Purchases_{i,t} + +\beta_3 RP\_Rec_{i,t} + \beta_4 RP\_Pay_{i,t} + \beta_5 CSRI_{i,t} \\ & + \beta_6 RP\_Sales * CSRI_{i,t} + \beta_7 RP\_Purchases * CSRI_{i,t} + \beta_8 RP\_Rec * CSRI_{i,t} + \beta_9 RP\_Pay \\ & * CSRI_{i,t} + \beta_{10} FAge_{i,t} + \beta_{11} FSize_{i,t} + \beta_{12} Lev_{i,t} + \beta_{13} ROA_{i,t} + \beta_{14} RPD_{i,t} + \beta_{15-21} Ind_{i,t} \\ & + \beta_{16} Year_{i,t} + \varepsilon \cdots\cdots\cdots\cdots\cdots\cdots\cdots.. \end{aligned} \tag{2}$$

where *FValue* = firm value as measured by Tobin's q and PBV; *RP_Sales* = the value of sales of goods and provision of services to related parties divided by total assets; *RP_Purchases* = the value of purchases of goods and receipt of services from related parties divided by total assets; *RP_Rec* = related party receivables divided by total assets; *RP_Pay* = related party payables divided by total assets; *CSRI* = CSR reporting as measured by observing a firm's CSR disclosure quantity (*CSRI_Quan*) and quality (*CSRI_Qual*); *FAge* = natural logarithm of the number of years since listing; *FSize* = natural logarithm of a firm's total market value of equity; *Lev* = total debts scaled by total assets; *ROA* = net income scaled by average total assets; *RPD* = RPT disclosure regarding terms and conditions, pricing policy and arm's length condition of RPTs.

4. Results

This section presents the data analysis, including the descriptive statistics and regression analysis. The final number of observations in the sample is 274 firm-year observations. The sample selection is described in Table 1.

4.1. Descriptive statistics

Table 2 provides a summary of the descriptive statistics of the variables. It shows that although loans provided to and given by related parties are less prevalent, related party sales transactions are common in firms

Please cite this article in press as: Hendratama, T.D., Barokah, Z. Related party transactions and firm value: The moderating role of corporate social responsibility reporting. China Journal of Accounting Research (2020), https://doi.org/10.1016/j.cjar.2020.04.002

Table 1
Sample Selection.

Criteria	Number of Firms		Number of Observations
	2014	2015	
Firms listed on Indonesia Stock Exchange (IDX)	514	533	1.047
Less: Firms in the financial industry	(87)	(90)	(177)
Less: Firms with a different fiscal year	(6)	(6)	(12)
Less: Firms with a negative book value of equity	(18)	(20)	(38)
Less: Firms with incomplete data	(272)	(274)	(546)
Total	131	143	274

listed in Indonesia. The results also show that the market value of firms listed on the IDX is generally higher than their book value as indicated by the mean values of 1.7749 and 2.7771 for Tobin's q and PBV, respectively. Moreover, the results indicate that Indonesian firms may put more emphasis on CSR reporting quantity than CSR reporting quality; nevertheless, the disclosure of CSR is still not a common practice among firms, and therefore, CSR reporting by Indonesian firms is still relatively limited.

4.2. Main results

Table 3 presents the analysis of the influence of RPTs on firm value. The results show that the first hypothesis, which states that related party sales negatively influence firm value, is supported ($p < .01$ and $p < .05$, respectively). These findings are consistent with studies suggesting that related party sales are value destroying (e.g., Cheung et al., 2006, 2009). This implies that the market views related party sales figures to be less credible and such transactions to be opportunistic (Jian and Wong, 2004); therefore, the market responds negatively to RPTs.

Contrary to expectation, Hypothesis 1b, which predicts a positive influence of related party purchases on firm value, is not supported because the coefficients of related party purchases are not significant in either model. This implies that related party purchase transactions are not used by related parties to prop up listed firms. A possible explanation for this non-significance may be that as the last-in-first-out (LIFO) method is not allowed, related parties may prefer other methods, which may be more timely and efficient, to prop up listed firms (Jian and Wong, 2010).

In addition, the results show that Hypothesis 1c is not supported, as there is no statistically significant association between related party receivables and firm value, suggesting that the market does not discount firms with high related party receivables. This may be due to the nature of related party receivables, which contain all types of receivables, including loan receivables that may be perceived negatively and sales receivables that may signify an increase in earnings and market confidence in the collection of related party credits (Jiang et al., 2010; Utama and Utama, 2014). According to Wang and Ye (2014), receivables represent the reallocated resources of a firm, namely operational and non-operational reallocated resources. Whereas operational resources are derived from activities such as the sale of goods and services, non-operational receivables may arise from non-operating activities such as loans. Consequently, receivables generated from the sale of goods and services are viewed as part of a firm's normal operating activities; whereas other receivables are non-operational and are often used opportunistically. Therefore, the efficiency and expropriation effects of related party receivables may offset each other, leading to non-significant results.

Regarding H1d, the empirical results show that related party payables positively influence Tobin's q and PBV ($p < .01$); therefore H1d is supported. This is in line with Cheung et al. (2006) who suggest that related party payables are viewed as beneficial by the market. Hence, related party payables tend to have a value-enhancing effect.

The empirical results in Tables 4 and 5 show that the coefficients of the interaction terms between CSR reporting (quantity and quality) and *RP_Sales* on Tobin's q as well as PBV are significant at the 1% and 5% levels, respectively. Hence, Hypothesis 2a, which states that CSR reporting moderates the relationship between related party sales and firm value, is supported. This confirms the view that CSR reporting reflects

a firm's corporate values and ethical concerns (Garriga and Melé, 2004; Kim et al., 2012). As a result, firms with strong ethical values as reflected by high quantity and quality CSR reporting tend to have less opportunistic RPTs. However, we do not find support for the moderating effect of CSR reporting on the relationship between other types of RPTs on either firm value measure. Although the coefficients are generally positive, the results are not significant. Nonetheless, this may provide initial but mild support for the negative relationship between CSR reporting and abusive behavior. Overall, our findings suggest that on the basis of ethics, firms with better CSR reporting tend to engage in more responsible operating decisions. Therefore, such firms are less likely to engage in opportunistic and value-destroying transactions that may harm the interests of minority shareholders, but rather they engage in efficient (value-enhancing) transactions.

The empirical results also show that the control variables, namely, firm age (*FAge*), firm size (*FSize*), leverage (*Lev*) and profitability (*ROA*) affect both Tobin's q and PBV with *p*-values less than 1%. More specifically,

firm age affects firm value negatively; whereas firm size, leverage and profitability affect firm value positively. This suggests that firms may become less valuable with age (Chay et al., 2015; Fauver et al., 2017). Moreover,

Please cite this article in press as: Hendratama, T.D., Barokah, Z. Related party transactions and firm value: The moderating role of corporate social responsibility reporting. China Journal of Accounting Research (2020), https://doi.org/10.1016/j.cjar.2020.04.002

the market values larger firms more positively (Dang et al., 2017), perceives increased leverage as a signal of stability in future cash flows (Ararat et al., 2017; Kang et al., 2017) and values firms with better performance more highly (Xia, 2008; Chen et al., 2009). In contrast, the coefficients of RPD are insignificant, implying that RPD does not influence firm value.

5. Test of subsequent tunneling

Further testing examines whether RPTs are of a propping nature and indeed add real value to a firm or merely boost performance temporarily and, in turn, enable subsequent tunneling. Ying and Wang (2013) posit that although there is a motivation to support the long-term interests of listed firms, when firms engage in RPTs for short-term purposes, such as to obtain a refinancing qualification, subsequent tunneling may occur in the year after such propping. Moreover, although certain RPTs improve current performance, due to subsequent tunneling, firm performance significantly declines in the following year. This study follows Ying and Wang (2013) and uses a model to test whether RPTs represent temporary propping transactions and enable subsequent tunneling activities.

$$Tunnel_{i,t+1} = r_0 + r_1 Prop_{i,t} + State_{i,t} + \varepsilon \cdots\cdots\cdots\cdots \tag{3}$$

$Prop_{it}$ represents the possible propping (value-enhancing) transactions found in this study. $State_{it}$ is a control variable measured by a dummy variable that takes the value of 1 for state-owned enterprises and 0 otherwise. Following Ying and Wang (2013), who find that state-owned enterprises display significantly more subsequent tunneling behavior than non-state-owned enterprises, this study includes $State_{it}$ as a control variable. Similarly, Cheung et al. (2009) examine RPTs between state-owned Chinese firms and find that minority shareholders seem to be subject to expropriation through tunneling, negatively affecting firm value.

$Tunnel_{i,t+1}$ is a dummy variable derived from the residual term of Eq. (4), which indicates possible abnormal tunneling in the following period. As Eq. (3) considers only possible abnormal tunneling transactions, this study removes the normal components of RPTs that are associated with firm characteristics and industry classifications following Jian and Wong (2010, 84) and using the following regression equation.

$$\begin{aligned} Tunnel\_rate_{i,t+1} = {} & r_0 + r_1 FSize_{i,t+1} + r_2 Lev_{i,t+1} + r_3 MBRatio_{i,t+1} + +r_j \sum Ind_{i,t+1} + r_j \sum Year_{i,t+1} \\ & + \varepsilon \cdots\cdots\cdots. \end{aligned} \tag{4}$$

This regression model removes the normal components of RPTs by adding variables associated with firm characteristics and industry classifications, such as size as measured by the natural logarithm of total assets, leverage as measured by total debt over total assets and growth as measured by market-to-book equity. This study also adds industry and year dummy variables. $Tunnel\_rate_{i,t+1}$ represents the ratio of the following period's possible tunneling arising from the purchase of goods or assets, guarantees, mortgages and other projects that generate income for related parties (Ying and Wang, 2013).

The results in Table 6 show that the coefficient of *Prop* is positive and significant, suggesting that transactions that boost current performance may actually be subject to subsequent tunneling as pointed out by Ying and Wang (2013). Further, these results suggest that state-owned enterprises display more subsequent tunneling behavior. This provides an early indication that RPTs may be subject to subsequent tunneling after propping.

6. Sensitivity tests

We also performed sensitivity tests for possible fixed effects. We re-estimated the models controlling for individual firm and year fixed effects in each model. Table 7 reports the results for Model 1 (main effects), and Tables 8 and 9 report the results for Model 2 (moderating effects).

As shown in Table 7, *RP_Sales* is now positive but not significant ($p > .10$). *RP_Purchases* has a positive and marginally significant relation with Tobin's q ($\beta = 0.016$, $p < .1$), consistent with H1b. *RP_Receivables* shows a negative and marginally significant association with Tobin's q ($\beta =$ -0.015, $p < .1$), in line with H1c. *RP_Payables* has a positive and significant association ($p < .001$) with both measures of firm value,

i.e., Tobin's q ($\beta = 0.023$, $p < .01$) and PBV ($\beta = 0.040$, $p < .01$), consistent with H1d. We re-run the model including each type of related party transaction (i.e., *RP_Sales*, *RP_Purchases*, *RP_Rec*, *RP_Pay*) separately and control for year and firm fixed effects. The results are similar. The result on *RP_Sales* differs from the main effect after controlling for firm fixed effects, indicating that there are other firm-specific factors that affect firm value that are not controlled in this study. For example, previous studies find that Indonesian firms with political connections are associated with higher firm value (Fisman, 2001). Further, Habib et al. (2017) argue that politically connected firms tend to engage more in abusive or opportunistic RPTs, which eventually affects firm value. Specifically, they find that politically connected firms in Indonesia are more likely to use related party loans to tunnel resources and to involve in earnings management. Furthermore, a study in the U.S. context finds that family firms are more likely to engage in RPTs and that their firm value premium tends to decline when they report RPTs, particularly opportunistic RPTs (Kohlbeck et al., 2018).

Hypotheses 2a-2d test the moderating effect of CSR reporting on the association between RPTs and firm value. We re-estimate Model 2 controlling for firm and year fixed effects. Tables 8 and 9 present the results for Eq. (2), considering CSR quantity and quality as moderating variables. The empirical results show that the associations between the interaction terms of CSR reporting (quantity and quality) and *RP_Purchases* with Tobin's q and PBV are significant at the 1% and 5% levels, respectively. The results for the moderating effects of CSR differ from the main effect after controlling for firm fixed effects, indicating that there are other firm-specific factors affecting firm value that are not controlled in this study, for example, political connections (Fisman, 2001; Habib et al., 2017) and family ownership (Kohlbeck et al., 2018).

7. Conclusion, implications and future research

This study provides evidence that concerns regarding RPTs being value destroying and value enhancing are warranted, particularly for certain types of RPTs. The results of all models show that related party sales transactions have a value-destroying effect. Further, we find that related party payables are positively related to both Tobin's q and PBV, suggesting that the market perceives loans or cash assistance provided to listed firms as beneficial. As certain RPTs are found to be abusive (value destroying), it is important that those transactions be reviewed and disclosed properly to ensure that such transactions are conducted in the best interest of stakeholders. Hence, to improve market confidence, regulators should pay more attention to the RPT types that tend to be abusive.

Further, this study provides evidence of moderating effects of both the quantity and quality of CSR reporting on the relationship between RPTs and firm value. Particularly, firms with high CSR reporting quantity and quality tend to have less abusive RPTs. Therefore, investors, policymakers and other stakeholders are encouraged to pay attention to both the quantity and quality of CSR reporting. More importantly, an assurance service and standard could be established to provide guidance for the preparation of CSR reports and to ensure the credibility of a firm's CSR reporting.

This study has several limitations and hence suggestions for future studies are offered. First, the main results differ slightly when individual firm fixed effects are included in the model. As presented in the sensitivity tests section, the statistical results show that firm value is positively influenced by related party purchases and payables, suggesting that these transactions have value-enhancing effects. In addition, firm value is negatively influenced by related party receivables, indicating a value-destroying effect. However, there is no support for

related party sales. In addition, robustness tests support the negative moderating effect of CSR on the association between related party purchases and firm value. These different results, compared with the main effects, indicate that there are other firm-specific variables that explain the dependent variables. A future study could consider other firm-specific factors such as political connections (Fisman, 2001; Habib et al., 2017) and family control (Kohlbeck et al., 2018) as explanatory variables. Second, this study only considers related party sales, purchases, receivables and payables. Therefore, future studies could consider other types of RPTs or break the RPT categories examined in this study into more detailed components. Further, future studies could explore other possible determinants of opportunistic RPTs, such as the risk of expropriation arising from a firm's ownership structure, corporate governance and financial constraints. Last, this study provides an early indication of the occurrence of tunneling after propping; future studies could further confirm this indication.

Declaration of Competing Interest

The authors declared that there is no conflict of interest.

ABSTRACT

We study how biases in financial reporting affect managers' incentives to develop innovative projects and to make appropriate investment decisions. Conservative reporting practices impose stricter verification standards for recognizing good news, and reduce the chance that risky innovations will lead to favorable future earnings reports. Holding all else constant, more conservative reporting therefore weakens the manager's incentive to work on innovative ideas, consistent with informal arguments in the extant literature. However, all else does not stay constant because the manager's pay plan will change in response to changes in the accounting system. We show that under optimal contracting, more conservative accounting does not stifle innovation in organizations, but rather increases incentives for innovation, as long as conservatism reduces the risk of an overstatement.

1. Introduction

This paper studies the role of conservative financial reporting on investment efficiency and innovation in corporations. Conservative accounting practices and innovation seem to conflict with one another. On the one hand, innovation requires an environment that protects managers from failure and encourages risk-taking (Manso, 2011; Reis, 2011). On the other hand, conservative reporting practices impose stricter verification standards for recognizing good news relative to bad news (Basu, 1997; Watts, 2003), and reduce the chance that risky investments will translate into favorable earnings reports. Conservatism may thereby foster prudence and risk avoidance, and inhibit innovation in organizations.

What is missing from this intuition, however, is the role of incentive contracting. Corporate boards design optimal incentive pay plans to control managerial actions, and these incentive plans will change when the reporting system changes. The aim of this manuscript is to examine how conservative accounting practices affect innovation in organizations taking into account optimal incentive contracting. We find that contrary to conventional wisdom, more conservative accounting does not impede innovation, but instead fosters innovation. Understanding the relation between conservative accounting rules and incentives for innovation is important, as innovation is vital for the continued growth of the economy.

☆ We thank Anne Beyer (the referee) and Michelle Hanlon (the editor) for many excellent comments and suggestions. We also thank Jeremy Bertomeu, Judson Caskey, Viktoria Diser, Robert Goex, Christian Laux, Paul Newman, Ulf Schiller, Raghu Venugopalan, and seminar participants at the University of Miami, University of Houston, University of Zurich, UC San Diego, George Mason University, UT Arlington, and College of William and Mary for their valuable comments.

We consider a model that captures the following key features of innovation: (i) the manager must spend costly effort to develop innovative ideas, and more effort increases the probability that her idea is viable; (ii) after the manager has worked on the innovation, she privately observes a signal about its success probability and chooses to either implement the innovation or continue with the status quo; (iii) pursuing the innovation is more risky than maintaining the status quo; and (iv) the innovation generates results in the long run.

Due to the long-term nature of innovation, the manager's compensation is linked to an interim earnings report that is informative about the firm's economic performance. We define the firm's accounting system as being more conservative when the verification requirements for issuing a favorable report are more stringent. More conservative accounting policies therefore render the firm less likely to issue a favorable report, but if it does issue a favorable report, it is a more accurate indicator that firm performance is indeed high.

The extant informal accounting literature evaluates conservative accounting by how it *directly* affects innovation and investment efficiency, taking other governance tools, such as incentive contracting, as exogenously fixed. Our model generates results that are similar to the arguments presented in the literature if we also view the manager's pay plan as exogenous. Specifically, since a shift to more conservative accounting reduces the probability that risky investments translate into favorable future earnings reports, conservatism weakens the manager's incentive to spend effort developing innovative ideas, consistent with arguments in Chang et al. (2015). Conservatism not only affects the manager's ex ante effort incentive, but also her decision whether to invest in the new idea ex post based on her private information about its profitability. More conservative accounting renders investing in the innovation less attractive for the manager, which improves investment efficiency if the manager is inclined to overinvest in the innovation, but aggravates investment efficiency if she is inclined to underinvest in the innovation, consistent with arguments in Roychowdhury (2010). Given these effects, more conservative accounting can either decrease or increase firm value.

While these arguments are intuitive, the desirability of conservative accounting should be evaluated in a broader framework that takes into account that contracts are chosen optimally and that contracts change when the reporting environment changes. In our setting, when designing the optimal pay plan, the board must address two incentive problems: motivate the manager to spend effort on developing innovative ideas, and induce her to make an efficient investment decision based on her private information about the innovation's success probability. These two incentive problems, however, conflict with each other. The optimal contract that encourages the manager to work hard on developing innovative ideas induces her to invest in an innovation even when its success probability is relatively low. Due to this tension, the optimal contract implements two types of inefficiencies: insufficient innovation effort and overinvestment in the innovation relative to first-best.

We are interested in how an increase in conservative accounting affects these agency frictions, and hence the manager's equilibrium actions. As discussed earlier, holding all else equal, an increase in conservatism reduces the probability that risky investments lead to favorable future earnings reports, and hence weakens the manager's incentive to work on innovative ideas. All else does not stay equal, however. We find that the board responds to an increase in conservatism by offering the manager stronger incentives to innovate. As a result, conservatism does not impair, but fosters innovation in organizations. The intuition for this result is as follows. By imposing stricter verification requirements for issuing a favorable report, conservative accounting increases the probability that a favorable report is an accurate representation of firm performance. This feature of conservatism allows the board to design incentive contracts that tie the manager's pay more closely to the profitability of the innovation. Offering a pay plan that is more sensitive to the innovation's profitability is beneficial not just because it induces the manager to work harder on developing innovative ideas. Rather, the advantage of a higher pay-performance sensitivity is that it induces higher innovation effort *without* creating excessive incentives to subsequently overinvest in the innovation. In short, more conservative accounting enables the board to better tackle the twin problems of inducing effort and efficient investment, and thus reduces contracting frictions.

As long as an increase in conservative accounting reduces the risk of an overstatement (which permits the board to offer contracts with a higher pay-performance sensitivity), an increase in conservatism (i) increases the manager's incentive to work on innovative ideas, (ii) reduces the manager's incentive to overinvest in an innovation, and (iii) ultimately increases firm value. Overall, our results indicate that conservative accounting does not discourage innovation in organizations, as is typically argued, but instead encourages innovation. Our model should not be interpreted, however, as predicting that firms will always adopt conservative reporting practices that eliminate the risk of overstatements because in practice there are other forces, besides the ones discussed here, that will also influence the firm's choice of conservatism (see the discussion in Section 7).

Our paper fuses together two streams of the analytical conservatism literature. The first stream examines the effect of conservatism on investment efficiency (Gigler et al., 2009; Li, 2013; Nan and Wen, 2014; Caskey and Laux, 2017). In this literature, the principal (e.g., the board of directors or the lender) makes an investment or abandonment decision based on a public accounting report that is informative about the profitability of the project. A conservative reporting system reduces the probability that the principal invests in a failing project (Type II error) but increases the probability that she foregoes a profitable project (Type I error). If the expected cost of Type II errors exceeds (is exceeded by) the expected cost of Type I errors, the principal optimally designs an accounting system with a conservative (aggressive) bias. In contrast, in our study, the manager is in charge of the investment decision, and she bases this decision not on a public accounting report but on private information. The bias in the accounting system nevertheless matters for the manager's investment choice because, ceteris paribus, conservative accounting reduces the likelihood that risky investments will translate into favorable earnings, which reduces the manager's willingness to take risks ex ante.

The second stream of literature focuses on the role of conservatism for contracting under moral hazard and limited liability (e.g., Balsmeier et al., 2017; Kwon, 2005; Kwon et al., 2001). These studies show that conservatism reduces the expected bonus required to induce the manager to take a certain effort level. The reason behind this result is that conservatism renders a high accounting report more informative about the manager's effort (that is, the likelihood ratio of the high report increases).[1] In contrast, in our setting, if the only problem were to induce the manager to spend effort developing an innovation, the bias in the accounting system would be irrelevant. It is the combination of both the effort moral hazard problem and the investment adverse selection problem that creates a role for conservative accounting. We contribute to the literature on conservatism by providing a formal discussion of how conservative accounting relates to optimal contracting, investment efficiency, and innovation.

Other papers that study the dual problems of inducing effort and efficient interim decisions include, e.g., Lambert (1986), Levitt and Snyder (1997), and Laux (2008). These studies show that providing the manager with effort incentives comes at the cost of encouraging inefficient interim actions, such as overinvestment or CEO entrenchment. However, these papers do not study the effects of conservative accounting policies. We show that more conservative accounting allows the board to design contracts that can better address the dual problems of inducing effort and efficient investment. Conservative accounting therefore results in contracts that lead to greater innovation effort, more efficient investment, and higher firm value.

2. Model

We consider a model with two risk-neutral players: shareholders, represented by a benevolent board of directors, and a manager. The manager is responsible for the dual tasks of developing new investment opportunities and deciding whether to invest in the new opportunity based on a privately observed signal about its profitability. The board's task is to set up the firm's financial reporting system and to design the incentive contract for the manager. The timeline and the details of the model follow.

2.1. Timing

There are five dates. At date 1, the board designs the accounting system and the incentive contract. At date 2, the manager expends effort to work on new investment ideas. At date 3, the manager privately observes the success probability of the investment idea and decides whether to implement it or continue with business as usual. At date 4, the accounting system generates a public report that is informative of the long-term cash flows of the firm. Long-term cash flows, denoted by X, are realized at date 5 after the contract with the manager has expired. Hence, X cannot be used for contracting purposes.

2.2. Innovation effort

The manager has an investment idea that is either viable or nonviable. The viable idea succeeds with probability θ, where θ is drawn from a distribution $F(\theta)$, with density $f(\theta)$ and full support over the interval $[0,1]$. The nonviable idea has a success probability of zero, $\theta = 0$. As will become apparent below, the manager always prefers to reject a nonviable investment idea since it fails with certainty. The manager can take a costly and unobservable action $a \in [0,1]$ to increase the probability that her idea is viable. Specifically, with probability a the idea is viable, and with probability $(1-a)$ it is nonviable. The manager's personal cost of effort a is $0.5ka^2$, where $k > 0$ is a constant. We assume the parameter k is sufficiently large to ensure an interior solution with $a < 1$.

2.3. Project choice

After choosing effort, the manager privately learns the profitability θ of the new investment idea and decides whether to implement it or continue with business as usual. If the manager invests in the new project, the project succeeds with probability θ, yielding a future cash flow of X_h, or fails with probability $(1-\theta)$, yielding a future cash flow of X_l. If the manager continues with business as usual, cash flow is $X_m > 0$, where $X_h > X_m > X_l \geq 0$.

2.4. Accounting report

The firm issues a contractible report $R \in \{R_h, R_m, R_l\}$ that is informative about the future cash flow X.[2] If the manager continues with business as usual, there is no uncertainty, and the report is $R = R_m$, representing cash flow X_m. If the manager implements the risky innovation, the accounting report is either high $(R = R_h)$ or low $(R = R_l)$. The mapping from the output $X \in \{X_h, X_l\}$ to the report $R \in \{R_h, R_l\}$ follows a two-step process (see, e.g., Kwon et al. (2001), Dye (2002), and Gao (2015)). In

[1] Gigler and Hemmer (2001) find that aggressive accounting can reduce the cost of inducing effort in a setting in which the manager is not protected by limited liability, but instead is risk averse.

[2] While the report R can be interpreted as either an internal or external report, we focus here on external reports. This allows us to contribute to the growing literature that studies how external financial reporting systems influence investment decisions and other managerial actions.

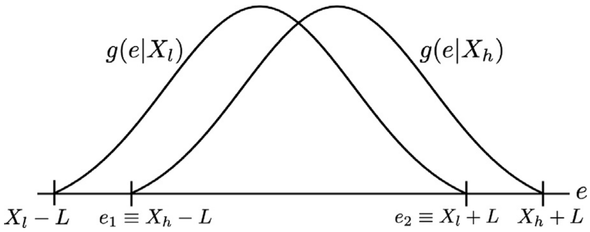

Fig. 1. A graphical illustration of the probability densities $g(e|X_l)$ and $g(e|X_h)$.

the first step, evidence $e = X + \varepsilon$ about the outcome is generated, where ε is drawn from a distribution with density $g(\varepsilon)$ and positive support over $(-L, L)$. Let $g(e|X)$ denote the probability density of e conditional on output X. Fig. 1 provides a graphical illustration of the probability densities.

We denote $e_1 \equiv X_h - L$ and $e_2 \equiv X_l + L$ and assume that $e_2 > e_1$. Thus, any evidence e below e_1 indicates a low output, $X = X_l$; any evidence above e_2 indicates a high output, $X = X_h$; and evidence in the range (e_1, e_2) is inconclusive about X. We make the standard assumption that the likelihood ratio $g(e|X_h)/g(e|X_l)$ is non-decreasing in e for all $e \in [e_1, e_2]$, that is, the monotone likelihood ratio property (MLRP) holds. This property implies that higher evidence e is good news since it indicates that the output is more likely high.

In the second step, the accounting system partitions evidence e into a binary report $R \in \{R_h, R_l\}$. Specifically, there is a threshold c such that the report is low, $R = R_l$, when $e < c$, and high, $R = R_h$, when $e \geq c$. The threshold c is observable to all players. Letting $p_{ij} \equiv \Pr(R_i|X_j)$ denote the probability that the accounting system generates report R_i when cash flow is X_j, with $i, j \in \{h, l\}$, we obtain:

$$p_{hh} = \int_c^{X_h+L} g(e|X_h)de \text{ and } p_{hl} = \int_c^{X_l+L} g(e|X_l)de, \tag{1}$$

$$p_{lh} = \int_{X_h-L}^{c} g(e|X_h)de \text{ and } p_{ll} = \int_{X_l-L}^{c} g(e|X_l)de. \tag{2}$$

The threshold c reflects a summary measure of the set of conditions that must be satisfied to issue a favorable report. An accounting system is more conservative when the requirements for a favorable report are more stringent, that is, when c is higher. This characterization is consistent with Basu (1997) and Watts (2003), who define conservative reporting practices as imposing stricter verification standards for recognizing good news than for recognizing bad news.

In practice, the degree of conservatism in a firm is determined collectively by the measurement principles the firm applies when it recognizes revenues, expenses or capitalizes development costs, impairs assets, recognizes loss contingencies, and values inventory. In general, when there is business uncertainty, more conservative accounting practices require the use of methods that are more likely to understate, rather than overstate, financial performance.

As an example, consider the treatment of research and development (R&D) costs, which can be either capitalized or expensed. Suppose expensing R&D costs leads to a low interim accounting report R_l while capitalizing R&D costs leads to a high report R_h. US-GAAP is conventionally considered more conservative than IFRS as it pertains to accounting for R&D costs. To illustrate how the accounting for R&D costs maps into the model note that higher evidence e indicates that the innovation is more likely successful. Whether R&D costs are expensed or capitalized is jointly determined by evidence e and the degree of conservatism c. Specifically, R&D costs are expensed when evidence e lies below the threshold c, resulting in R_l, and R&D costs are capitalized when evidence e exceeds the threshold c, resulting in R_h. A more conservative accounting regime is one that is characterized by a higher threshold c and implies that stronger evidence e of the project's future success is required for capitalization.[3]

In our setting (and the above R&D example), the report R does not directly depend on the manager's ex ante private information θ. Instead, the report depends on the evidence e and hence only indirectly on θ via X. It is useful to discuss the difference between θ and e. Both parameters are informative of the probability of project success but there is an important difference. θ is the manager's private information at the time she makes the investment decision and hence determines whether investing in the new project is efficient. If the report could be based on θ, the board would be able to tell if the manager made the efficient investment decision (which is to invest if θ exceeds the first-best threshold θ_{FB}, defined later). We show in Appendix A that in this case the optimal contract trivially implements the first-best investment decision (but not first-best innovation effort). In contrast, evidence e arrives only after the manager implemented the project and the evidence is not a clear indicator of whether the manager made the appropriate investment decision ex ante given the information she had at the time. This is because high evidence e could be the result of a manager who implemented the project despite a low θ,

[3] We thank the referee for suggesting we model conservatism as a threshold and for the R&D example discussed here.

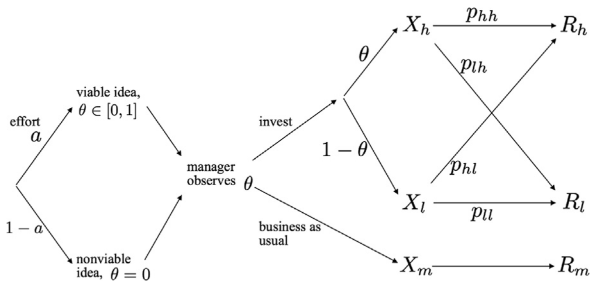

Fig. 2. Game tree of the model.

and simply was lucky. The accounting report R only captures how well the project is currently doing (evidence e) but cannot capture what the manager knew when she made the investment decision (θ). As a result, an incentive problem exists not only with respect to the manager's innovation effort but also with respect to her investment decision.

2.5. Contracting

At date 1, the board offers the manager a contract that specifies her payments contingent on the accounting report R. Specifically, the contract is given by $W = (w_h, w_m, w_l)$, where w_i denotes the manager's payment if $R = R_i$. The manager is protected by limited liability in the sense that payments must be nonnegative; that is, $w_i \geq 0$ for each $i = h, m, l$. The limited liability constraint restricts the board's ability to use punishments as a means to provide incentives. The board therefore has to rely solely on rewards as an incentive tool, which allow the manager to enjoy a positive utility. To guarantee contracting frictions, we make the standard assumption that the manager's reservation utility, $\underline{U}$, is below a certain threshold, denoted $\underline{U}_T$ (where $\underline{U}_T > 0$ is specified in (47) in Appendix D). This assumption implies that the rewards that induce the second-best actions yield the manager an expected utility that exceeds her reservation utility; that is, the manager reaps an economic rent. The board therefore faces a trade-off between the costs of granting the manager larger rents and the benefits of inducing more efficient actions.

Since the manager is privately informed about the profitability θ of the new project, the board grants the manager the authority to make the investment decision. We show in Appendix B that restricting attention to this simple contract is without loss of generality. To show this, we consider a contract in which the board retains investment authority and designs a general direct revelation mechanism that induces the manager to truthfully reveal her private information θ. This revelation mechanism does not outperform the simple contract we study.

Fig. 2 depicts the game tree of the model.

Before turning to the analysis, we briefly discuss the simplifying assumptions of the model.[4]

2.6. Distribution of θ

We assume in the model that innovation effort a increases the probability that the innovation is viable. An alternative modeling approach is to assume that the project's probability of success θ is drawn from a distribution $H(\theta|a)$ and that a higher innovation effort a shifts the probability distribution to the right in the sense of first-order stochastic dominance. This setting becomes intractable quickly, but is solvable when the effort choice is binary, $a \in \{a_l, a_h\}$. Similar to the present model, an increase in conservatism allows the board to better tackle the dual problems of inducing effort and efficient investment. An increase in c therefore leads to more efficient investment and higher firm value.

2.7. Output

In our setting, investing in the innovation leads to either a high or low report (R_h or R_l), whereas conducting business as usual involves no uncertainty and always leads to R_m. This assumption has two implications. First, the board can essentially contract on whether the manager has invested or not invested. Second, conservatism c only affects the report when the manager implements the risky innovation but not when she conducts business as usual. We can modify our setting so that the investment decision cannot be inferred from the report R and conservatism affects R even when the manager conducts business as usual. Specifically, suppose that implementing a viable project leads to a risky outcome with probability $\beta_I < 1$, in which case the outcome is high, X_h, with probability θ and low, X_l, with probability $(1-\theta)$. However, with probability $(1-\beta_I)$ the outcome is safe and $X = X_m$. In contrast, if the manager continues with business as usual, the outcome is risky with probability β_N, where $\beta_N < \beta_I$, in which case the high and low outcome are equally likely. With probability $(1-\beta_N)$ the

[4] Proofs are available upon request.

outcome is safe and $X = X_m$. The assumption $\beta_I > \beta_N$ captures the notion that investing in an innovation is more risky than conducting business as usual. The mapping from the output X to the report R is as before. We can show that as long as the probability of generating a high cash flow X_h is higher when the manager invests in an innovation than when she continues the status quo, our qualitative results continue to hold.

2.8. Number of reports

In our setting, the degree of conservatism c partitions evidence e into a binary report. Suppose instead that there are two thresholds, c_1 and c_2, with $c_1 < c_2$, that partition the evidence into three reports R_1, R_2, and R_3. In this case, the optimal contract rewards the manager for the highest report R_3 but not for the lower reports R_1 and R_2, since R_3 is most informative about the high cash flow X_h (which follows from the MLRP).[5] The threshold c_1 is then irrelevant and a change in c_2 has the same effects as a change in c in our one-threshold setting.

2.9. Reservation utility

As mentioned earlier, we focus on the case where the manager's reservation utility lies below a threshold $\underline{U}_T$ (specified in (47) in Appendix D). As is typical in limited liability settings, if the manager's reservation utility $\underline{U}$ exceeds a second threshold, which we denote by $\underline{U}_F$, the board can implement the first-best actions without leaving the manager any rents. In this case, there are no contracting frictions and the level of conservatism plays no role. However, $\underline{U}_F$ is so high that the manager must receive most of the output just to ensure her participation, leaving the shareholders with less than X_l. Since $\underline{U}_F > \underline{U}_T$, the only remaining case is the one where $\underline{U}$ lies between $\underline{U}_T$ and $\underline{U}_F$. In this case, the board cannot implement first-best actions without leaving the manager any rents and induces the highest actions that keep her at her reservation utility $\underline{U}$; that is, the manager's participation constraint determines the optimal actions. Assuming that $\underline{U} \in (\underline{U}_T, \underline{U}_F)$ does not change our main results that more conservative accounting leads to a higher innovation effort level and higher firm value (under optimal contracting).

3. Definition of conservatism

The firm's accounting system is more conservative when the requirements for a favorable report are more stringent, that is, when c is higher. This is consistent with the definition of conservatism in Gigler et al. (2009). Specifically, for any threshold $c \in [e_1, e_2)$ our setting satisfies Gigler et al.'s (2009) conditions (A1)-(A3). Translated into our setting, these conditions are as follows:[6]

(A1) The likelihood ratio $\frac{\Pr(R|X_h)}{\Pr(R|X_l)}$ is increasing in R: $\frac{p_{hh}}{p_{hl}} > 1 > \frac{p_{lh}}{p_{ll}}$.
(A2) For each outcome $X \in \{X_l, X_h\}$, the probability of a low report is increasing in c: $\frac{dp_{lh}}{dc} > 0$ and $\frac{dp_{ll}}{dc} > 0$.
(A3) The likelihood ratios $\frac{p_{hh}}{p_{hl}}$ and $\frac{p_{lh}}{p_{ll}}$ increase in c.

(A1) implies that the accounting report is informative about X, where R_h represents good news and R_l represents bad news. Thus, the posterior probability of a high (low) cash flow given a high (low) report exceeds the prior probability: $\Pr(X_h|R_h, \theta) > \theta$ and $\Pr(X_l|R_l, \theta) > (1 - \theta)$.

(A2) implies that more conservative accounting increases the probability that both X_h and X_l lead to a low rather than high accounting report. Intuitively, an increase in the threshold c strengthens the requirements that must be satisfied for a favorable report, and hence reduces the probability of a favorable report.

(A3) implies that conservative accounting increases the information content of the high report but reduces the information content of the low report:

$$\frac{d\Pr(X_h|R_h, \theta)}{dc} > 0 \text{ and } \frac{d\Pr(X_l|R_l, \theta)}{dc} < 0. \tag{3}$$

As the requirements for issuing a high report become more stringent (c increases), the high report becomes a better indicator of the high output X_h and the low report becomes a weaker indicator of the low output X_l.

When the threshold c reaches e_2, the requirements for issuing a high report are so stringent that the high report becomes a clear indicator that the firm's economic performance is high, $\Pr(X_h|R_h) = 1$. Any further increase in c above e_2 does not change the information content of R_h, but reduces the information content of R_l (since p_{lh} increases with c). Similarly, when c reaches e_1, the requirements for reporting good news are so weak that a low report becomes a clear indicator that economic performance is indeed grim, $\Pr(X_l|R_l) = 1$. Reducing c below e_1 does not change the information content of R_l, but reduces the

[5] This is related to standard agency models with limited liability and risk neutrality where the agent is rewarded only for the signal/output that is most informative of high effort.
[6] We show in Appendix C that conditions (A1)-(A3) follow from (1) and (2).

information content of R_h (since p_{hl} increases as c decreases). It is therefore without loss of generality to focus on the intermediate values $c \in [e_1, e_2]$ in what follows.

4. Managerial actions

In this section, we solve for the manager's effort and investment choices given contract W and determine the board's optimization problem. After the manager observes the profitability θ of the new investment idea, she decides whether to implement it or continue with business as usual. Conditional on θ, the manager's expected compensation if she implements the innovation is

$$\Omega(\theta) \equiv \theta E[w|X_h] + (1-\theta)E[w|X_l],$$

where

$$E[w|X_h] = p_{hh}w_h + p_{lh}w_l, \tag{4}$$

$$E[w|X_l] = p_{hl}w_h + p_{ll}w_l, \tag{5}$$

is the manager's expected pay when future cash flow is high, X_h, or low, X_l, respectively. We refer to $\Omega(\theta)$ as the manager's innovation compensation.

The manager invests in the innovation rather than continues business as usual if and only if:

$$\Omega(\theta) \geq w_m. \tag{6}$$

As will become clear later, the optimal contract W satisfies

$$E[w|X_h] > w_m > E[w|X_l]. \tag{7}$$

The first inequality in (7) implies that the manager's payoff is higher if she implements an innovation that succeeds with certainty than if she continues the status quo, and the second inequality implies that the manager's payoff is lower if she implements an innovation that fails with certainty than if she continues the status quo.

Given (7), there is a unique interior threshold, θ_T, that satisfies

$$\Omega(\theta_T) = w_m, \tag{8}$$

so that the manager implements the innovation if its profitability θ exceeds θ_T, and continues with business as usual otherwise.

At date 2, the manager chooses innovation effort a to maximize her ex ante utility

$$U = \Psi - 0.5ka^2, \tag{9}$$

where

$$\Psi = a\left(\int_{\theta_T}^{1} \Omega(\theta)f(\theta)d\theta + F(\theta_T)w_m\right) + (1-a)w_m \tag{10}$$

is her expected compensation. With probability a, the innovation is viable and the manager implements it if $\theta \geq \theta_T$, yielding her $\Omega(\theta)$, and continues the status quo if $\theta < \theta_T$, yielding her w_m. With probability $(1-a)$, the innovation is nonviable and the manager continues the status quo. Taking the first-order condition for a maximum yields:

$$a = \frac{1}{k}\int_{\theta_T}^{1} (\Omega(\theta) - w_m)f(\theta)d\theta. \tag{11}$$

Fig. 3 illustrates the manager's incentives graphically. We assume in the figure (and in all figures that follow) that the profitability θ of a viable project follows a uniform distribution over the interval $[0, 1]$. The manager's investment threshold θ_T is determined by the intersection between the expected pay she receives when pursuing the innovation, $\Omega(\theta)$, and the pay w_m she receives when conducting business as usual.

Region A in Fig. 3 represents the increase in the manager's ex ante compensation if she develops a viable idea, and hence determines her innovation effort incentive. Since the figure considers a uniform distribution, the manager's effort choice is $a = A/k$. The larger the region A, the larger the expected reward for developing a viable innovation and the higher the manager's incentive to expend innovation effort.

Given the manager's effort and investment choices, the firm's ex ante cash flow is:

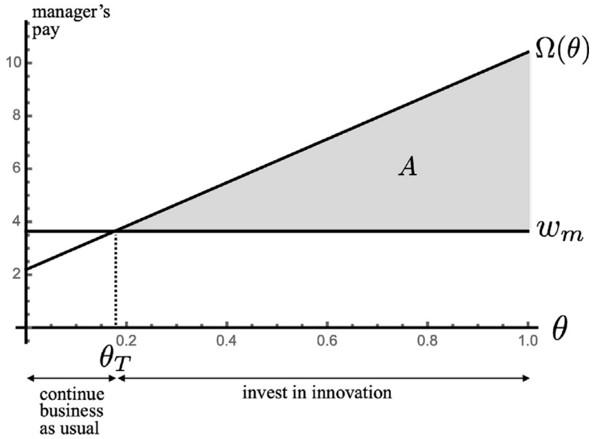

Fig. 3. A graphical illustration of the manager's investment threshold θ_T and her effort choice $a = A/k$.

$$CF = a\left(\int_{\theta_T}^{1}(\theta X_h + (1-\theta)X_l)f(\theta)d\theta + F(\theta_T)X_m\right) + (1-a)X_m. \tag{12}$$

The board's problem is now to maximize the expected firm value

$$\max_{(w_h, w_m, w_l, c)} \; V = CF - \Psi, \tag{13}$$

subject to the manager's incentive constraints (8) and (11), her participation constraint $U \geq \underline{U}$, and the limited liability constraints, $w_h, w_m, w_l \geq 0$. To ensure that the board's optimization problem is concave, we assume that the marginal cost of effort, k, is sufficiently high.[7]

As a reference, note that the first-best actions solve

$$\max_{(a,\theta_T)} CF - 0.5ka^2.$$

The first-best investment decision is to implement the innovation if and only if $\theta \geq \theta_{FB}$, where θ_{FB} is defined by

$$\theta_{FB}X_h + (1-\theta_{FB})X_l = X_m \tag{14}$$

and the first-best innovation effort is

$$a_{FB} = \frac{1}{k}\int_{\theta_{FB}}^{1}(\theta X_h + (1-\theta)X_l - X_m)f(\theta)d\theta. \tag{15}$$

5. Benchmark: Effects of conservatism when the pay plan is exogenous

We start the analysis by considering how changes in the accounting system affect the manager's actions and firm value, assuming the contract W is held constant (but satisfies (7)). In this benchmark, our model generates results that resemble the informal arguments made in the literature.

The next proposition establishes how an increase in conservative accounting affects the manager's innovation effort a, her investment threshold θ_T, and her expected compensation Ψ. All proofs are in Appendix D.

Proposition 1. *Holding the contract W fixed, an increase in conservatism c:*

(i) *increases the investment threshold* θ_T;
(ii) *reduces the manager's innovation effort* a;
(iii) *reduces the manager's expected compensation* Ψ.

[7] See the proof of Proposition 2 for details.

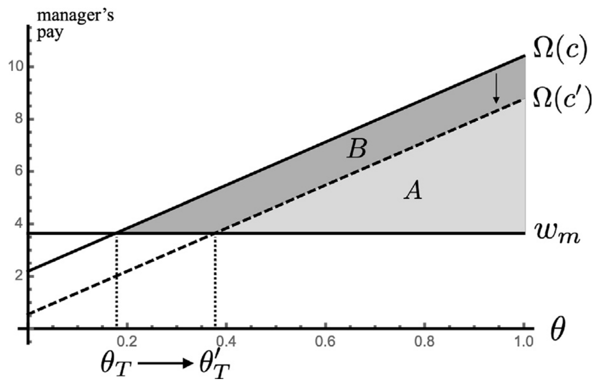

Fig. 4. An increase in conservatism from c to c' reduces the expected innovation compensation from $\Omega(c)$ to $\Omega(c')$, which increases the investment threshold from θ_T to θ_T', but reduces innovation effort by B/k.

When the accounting system is more conservative, investing in a risky innovation is less likely to result in a favorable earnings report. The manager's expected innovation compensation $\Omega(\theta)$ is therefore lower when the accounting system is more conservative for any given θ.[8] Fig. 4 depicts the decline in $\Omega(\theta)$ when conservatism increases from c to c'.[9]

The decline in the innovation compensation Ω associated with an increase in c renders the manager less eager to work hard on developing innovative ideas. The manager's innovation effort choice therefore declines from $a = (A+B)/k$ to $a' = A/k$ in Fig. 4. This result is consistent with the view put forth by Chang et al. (2015), who argue that conservative accounting stifles innovation in organizations.

Further, the degree of conservatism affects the manager's investment decision once she has made her effort choice. Specifically, the decline in Ω reduces the manager's incentive to invest in the innovation, and hence increases the investment threshold from θ_T to θ_T' in Fig. 4. Whether an increase in the threshold θ_T improves or worsens investment efficiency depends on whether the investment threshold initially lies below or above the first-best level θ_{FB}. If $\theta_T < \theta_{FB}$, the manager overinvests in the innovation for all $\theta \in [\theta_T, \theta_{FB})$ in the sense that she implements the new idea even though continuing the status quo is optimal for shareholders. More conservative accounting then reduces the manager's overinvestment incentive and pushes θ_T closer to θ_{FB}. The opposite is true when $\theta_{FB} < \theta_T$. In this case, the manager underinvests in the innovation for all $\theta \in (\theta_{FB}, \theta_T]$ and more conservative accounting aggravates the manager's underinvestment incentive and pushes θ_T further away from θ_{FB}. These findings are consistent with Roychowdhury (2010), who points out that conservatism is no panacea because it can alleviate as well as aggravate investment inefficiencies.

The level of c that maximizes firm value V balances the different effects on investment efficiency, innovation effort, and managerial compensation. Formally, the effect of a marginal increase in c on V is given by[10]

$$\frac{dV}{dc} = -a(\theta_T X_h + (1-\theta_T)X_l - X_m)f(\theta_T)\frac{d\theta_T}{dc} + \frac{da}{dc}\left[\frac{1}{k}\int_{\theta_T}^{1}(\theta X_h + (1-\theta)X_l - X_m)f(\theta)d\theta - 2a\right]k, \tag{16}$$

where θ_T and a satisfy (8) and (11), respectively. Conservative accounting influences firm value V via three channels. A higher degree of conservatism (i) leads to a higher investment threshold θ_T, (ii) weakens ex ante innovation effort incentives, and (iii) reduces the manager's expected compensation. Effect (i) is captured in the first line in (16) and effects (ii) and (iii) are captured in the second line in (16). These effects can lead to an interior optimal level of conservatism. For example, when $X_h = 200, X_m = 140, X_l = 100, w_h = 4, w_m = 2, w_l = 0, k = 1, g(e|X_h) = g(e|X_l) = 1/(2L), L = 100$, and $f(\theta) = 1$, firm value V is single peaked with respect to c and the optimal c is 111.3. For the optimal level of c the investment threshold and effort level are $\theta_T = 0.12$ and $a = 0.77$, respectively, which lie below the first-best levels of $\theta_{FB} = 0.4$ and $a_{FB} = 1$. In this example, the optimal value of c is relatively low, which has the benefit of inducing a high level of innovation effort but comes at the cost of overinvestment, $\theta_T < \theta_{FB}$, and a high expected managerial compensation. An increase in c would lead to more efficient investments and less managerial compensation, but the associated decline in innovation effort would more than offset these benefits.

[8] Formally, using (4) and (5) and recognizing that $p_{ll} = (1-p_{hl})$ and $p_{lh} = (1-p_{hh})$, the manager's innovation compensation can be written as $\Omega = (\theta p_{hh} + (1-\theta)p_{hl})(w_h - w_l) + w_l$, which decreases with c for all θ since $dp_{hh}/dc < 0$, $dp_{hl}/dc < 0$, and $w_h > w_l$.

[9] To ease exposition, Fig. 4 (and all figures that follow) assumes $dp_{hh}/dc = dp_{hl}/dc$, so that an increase in c reduces the intercept of the innovation compensation Ω but not its slope.

[10] Equation (16) is obtained by taking the first derivative on (13) and using (28).

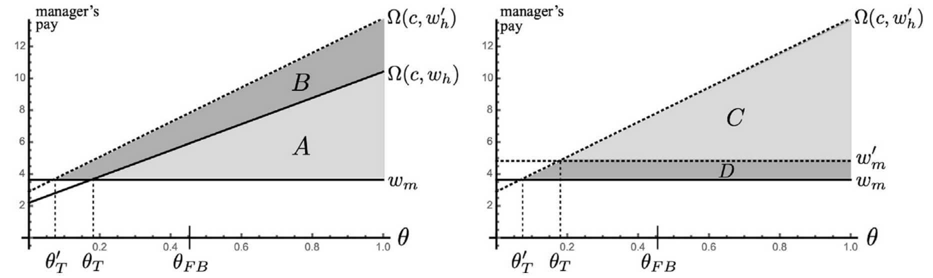

Fig. 5. The left panel shows that an increase in the pay w_h to w'_h increases the innovation compensation $\Omega(c, w_h)$ to $\Omega\left(c, w'_h\right)$, which increases effort incentives by B/k, but reduces the investment threshold θ_T to θ'_T. The right panel show that an increase in the pay w_m to w'_m increases the investment threshold back to θ_T, but reduces effort incentives by D/k.

6. Optimal contracting

We now take into account that incentive contracts are chosen endogenously and that they will be adjusted in response to changes in the accounting system. Allowing for optimal contracting leads to conclusions that differ significantly from those in the benchmark section. Specifically, we find that more conservative accounting practices do not result in weaker managerial incentives to work on innovative projects, but result in stronger innovation effort incentives. Further, conservatism always leads to more efficient investment and higher firm value.

Our analysis proceeds in two steps. In Subsection 6.1, we show that the optimal pay plan that motivates the manager to work on an innovation induces her to subsequently overinvest in innovation. Due to this tension, the optimal effort level and investment threshold lie below the first-best levels, $a^* < a_{FB}$ and $\theta_T^* < \theta_{FB}$. We then show in Subsection 6.2 that more conservative accounting alleviates the tension between inducing effort and inducing efficient investment, and thus results in less overinvestment, greater innovation effort, and higher firm value.

6.1. Tension between inducing effort and efficient investment

When designing the contract W the board has to address two incentive problems: motivating the manager to work on developing a viable innovation, and inducing her to make an efficient investment decision based on her private information about the innovation's profitability θ. These two incentive problems conflict with one another. To see why consider the left panel of Fig. 5 and suppose the pay plan (w_h, w_m, w_l) depicted there implements actions that are below first-best, $\theta_T < \theta_{FB}$ and $a < a_{FB}$.[11]

If the board wishes to boost the manager's incentive to work on an innovation, it can do so by increasing the manager's bonus w_h for a high accounting report, say to w'_h. The higher bonus increases the innovation compensation from $\Omega(c, w_h)$ to $\Omega\left(c, w'_h\right)$, and hence the manager's effort level from $a = A/k$ to $a' = (A+B)/k$, as depicted in the left panel of Fig. 5. The higher bonus, however, has two drawbacks. First, it increases the manager's expected compensation, and second, it boosts the manager's incentive to overinvest in a viable innovation, reducing the investment threshold from θ_T to θ'_T. The board's goal of inducing effort therefore conflicts with its goal of inducing efficient investment.

The board can counteract the manager's stronger overinvestment incentive by offering a greater reward for continuing business as usual, w_m. When w_m increases to w'_m, as depicted in the right panel of Fig. 5, the manager's investment threshold increases back to the initial level θ_T. But rewarding the manager for doing business as usual increases the manager's pay, and also weakens her incentive to innovate. The manager's innovation effort therefore declines by D/k. To preserve incentives for innovation effort, an increase in w_m must be combined with an increase in the bonus w_h, which further increases the cost of the incentive system, and so on.

Due to these interactions and costs, the optimal contract implements actions that lie below the first-best levels, $\theta_T^* < \theta_{FB}$ and $a^* < a_{FB}$, as stated in the next proposition. The optimal pay plan (w_h, w_l, w_m) that implements the optimal actions can be found in Appendix D.

Proposition 2. *For any level of conservatism c, the optimal contract induces the manager*

(i) *to exert too little innovation effort,* $a^* < a_{FB}$, *and*
(ii) *to overinvest in a viable innovation,* $\theta_T^* < \theta_{FB}$,

relative to the first-best levels.

[11] The contract (w_h, w_m, w_l) depicted in Fig. 5 is actually the optimal contact when $k = 5$, $X_h = 110$, $X_l = 0$, $X_m = 50$, and $p_{hh}(c) = 0.95$, $p_{hl}(c) = 0.2$.

6.2. The value of conservative accounting

We are now ready to study the benefits of conservative accounting practices. The analysis proceeds as follows. We first show that conservatism alleviates the contracting tensions that we discussed in the previous subsection. We then show that more conservative accounting leads to contracts that implement greater innovation effort and more efficient investment, and ultimately increases firm value.

We know from Section 6.1 that offering the manager a higher bonus w_h spurs her incentive to work on the innovation, but has the downside of creating stronger incentives for overinvestment. Proposition 3 shows that an increase in both w_h and c allows the board to boost the manager's innovation effort incentive without increasing her incentive for overinvestment.

Proposition 3. *For all $c \in [e_1, e_2)$, a higher level of conservatism alleviates the tension between inducing effort and inducing efficient investment. Specifically, as c increases, the board can offer a larger bonus w_h to:*

(i) *increase innovation effort a, without increasing incentives for overinvestment (θ_T stays constant), or*
(ii) *reduce overinvestment incentives (increase θ_T), without reducing innovation effort (a stays constant).*

The intuition behind the result in Proposition 3(i) is as follows. When the accounting system is more conservative, investing in a risky innovation is less likely to result in a favorable earnings report. As a result, an increase in c reduces the manager's expected innovation compensation Ω for any given θ and the innovation becomes relatively less attractive (as discussed in the benchmark setting in Section 5). To hold the investment behavior constant, the board increases the bonus w_h so that the marginal type that is indifferent between investing and business as usual, θ_T, continues to be indifferent. Increasing the bonus w_h increases the expected innovation compensation $\Omega(\theta)$, and, importantly, the increase is higher for higher values of θ. As a result, investment becomes more attractive in expectation for any $\theta > \theta_T$, which fosters the manager's incentive to exert innovation effort. The key assumption underlying this result is that a higher degree of conservatism renders the high report more informative of high performance. The left panel of Fig. 6 demonstrates these effects graphically. An increase in the level of conservatism and the bonus from (c, w_h) to $\left(c', w'_h\right)$ renders the innovation compensation Ω more sensitive to the innovation's success probability θ, that is, the slope of Ω increases. This shift in Ω increases the manager's incentive to work on the innovation from $a = A/k$ to $a' = (A+B)/k$, but leaves her investment threshold θ_T unchanged.

As long as more conservative accounting increases the informativeness of the high report (that is, $d\frac{p_{hh}}{p_{hl}}/dc > 0$), the board can exploit an increase in c to tie the manager's innovation pay closer to θ, and hence better address the dual problem of inducing effort and efficient investment. This is the case until conservatism reaches $c = e_2$. Increasing c above e_2 does not further increase the information content of the high report, and hence has no effect on contracting.

Alternatively, the board can respond to an increase in c by adjusting the bonus w_h so that the manager's overinvestment incentive declines but her incentive for innovation effort remains constant (as stated in part (ii) of Proposition 3). This case is depicted in the right panel of Fig. 6, where the shift from (c, w_h) to $\left(c'', w''_h\right)$ increases the investment threshold from θ_T to θ''_T but leaves effort incentives unchanged, since $C = D$. The steeper performance sensitivity of Ω implies that the manager's incentive for innovation effort now comes mainly from highly profitable innovations. Thus, the manager is less inclined to overinvest in an innovation while her incentive to spend innovation effort remains unchanged.

Both cases demonstrate that more conservative accounting permits the board to better tackle the twin problems of encouraging the manager to work on innovative ideas and make efficient investment decisions. Since conservatism reduces agency frictions, an increase in c results in more efficient actions and higher firm value, as stated in Proposition 4.

Proposition 4. *For all $c \in [e_1, e_2)$, a higher level of conservatism*

(i) *increases the investment threshold θ^*_T and, hence, reduces overinvestment,*
(ii) *increases innovation effort a^*, and*
(iii) *increases firm value V.*

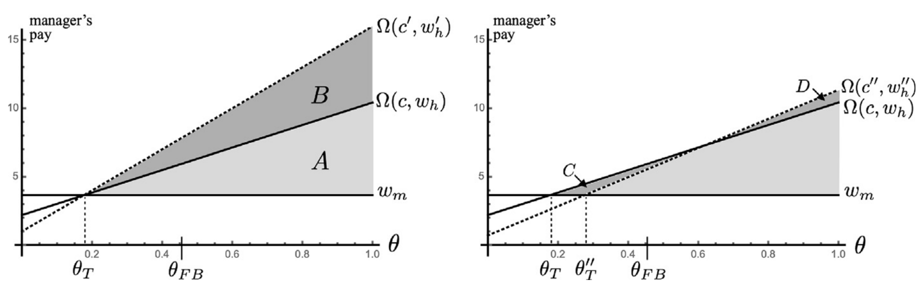

Fig. 6. The left panel demonstrates that an increase in conservatism and the bonus from (c, w_h) to $\left(c', w'_h\right)$ increases effort incentives by B/k, without changing the investment threshold θ_T. The right panel shows that a move to $\left(c'', w''_h\right)$ increases the investment threshold to θ''_T, without changing effort incentives, because $C = D$.

It is instructive to compare these results with the results from Section 5, where we treat the contract as exogenous. When $\theta_T < \theta_{FB}$, an isolated increase in the level of conservatism c has positive and negative effects on the manager's behavior: It reduces incentives for overinvestment but also weakens incentives for innovation effort. Due to this tension, an increase in c can increase or decrease firm value. The situation is different with endogenous contracts. The degree of conservatism is then no longer the only tool to influence the manager's behavior. Instead, the board relies on the manager's pay plan to address the incentive conflicts and the optimal contract balances incentives for innovation effort and incentives for efficient investment. A higher degree of conservatism allows the board to adjust the contract to better address these incentive problems, which renders an increase in c unambiguously valuable. Specifically, as discussed following Proposition 3, as long as a higher degree of conservatism increases the informativeness of the high report ($d\frac{p_{hh}}{p_{hl}}/dc > 0$), the board can exploit more conservative accounting to increase the sensitivity between the manager's innovation compensation Ω and the innovation's success probability θ. The higher pay-performance sensitivity, in turn, allows the board to better tackle the dual problems of inducing innovation effort and inducing efficient investment. As a result, whereas with exogenous contracts, conservatism stifles innovation, the opposite is true with endogenous contracts and an increase in c leads to more innovation effort. The discussion shows that optimal contracting critically changes the role of conservative accounting.

6.3. Optimal accounting system

From Proposition 4 we know that more conservative accounting reduces contracting frictions and yields a higher firm value until c reaches e_2. This result immediately leads to the next corollary.

Corollary 1. *The level of conservatism that maximizes firm value is* $c^* = e_2$

When the level of conservatism is chosen optimally, $c = e_2$, the requirements for issuing a high report R_h are so stringent that the firm can only report R_h if the evidence e clearly supports the good news (that is, $e \geq e_2$). Thus, if there is uncertainty about the output, the firm has to play it safe and understate, rather than overstate, financial performance.

We next determine the optimal pay plan and equilibrium actions when conservatism is chosen optimally. To do so, note that for $c = e_2 \equiv X_l + L$, the conditional probabilities in (1) and (2) change to

$$p_{hh} = \int_{X_l+L}^{X_h+L} g(e|X_h)de \text{ and } p_{hl} = 0, \tag{17}$$

$$p_{lh} = \int_{X_h-L}^{X_l+L} g(e|X_h)de \text{ and } p_{ll} = 1. \tag{18}$$

Substituting these probabilities into (29), (30), (40), (41), and (51) in Appendix D yields the optimal pay plan, managerial actions, and firm value.

Two observations are useful. First, when the level of conservatism is chosen optimally, $c = e_2$, the incentive problems discussed in Section 6.1 still prevail but are less severe relative to the case where $c < e_2$. Thus, the first-best solution cannot be achieved and the optimal contract implements an investment threshold and an innovation effort level below the first-best levels, $\theta_T^* < \theta_{FB}$ and $a^* < a_{FB}$.[12] Second, the fact that the contract can only be contingent on the earnings report R but not on the long-term output X does not negatively affect firm performance when the level of conservatism is chosen optimally (but does reduce firm value if c is suboptimal). Thus, for $c = e_2$, the optimal contract studied here leads to the same equilibrium actions and firm value that would result if the firm were able to write contracts that are directly contingent on long-term output. The reason is that the optimal earnings-based contract rewards the manager only for a high report, and the high report is a clear indicator of high firm performance when $c = e_2$.[13]

6.4. Stock-based compensation

In this subsection, we discuss the role of stock-based compensation. Stock-based compensation can be valuable when the stock price reflects information that cannot be captured in the accounting report R. For example, non-financial information about the long-term demand for the innovation is reflected in the stock price, but not in the accounting report.[14] Specifically, consider a modified setting, where the future output of the innovation X depends on two parameters: the project type, such as the implementability of the project, denoted T, with $T \in \{T_h, T_l\}$, and the long-term demand for the innovation, denoted δ,

---

[12] Formally, this can be seen by substituting $c = e_2$ into the first-order conditions for θ_T^* and a^* given in (40) and (41) and comparing these first-order conditions with the first-best actions determined in (14) and (15).

[13] To obtain the optimal solution when X is contractible, we do not need to redo the analysis, but merely set $p_{hh} = 1$ and $p_{ll} = 1$, because the report R is then a one-to-one mapping of the outcome X. When the board contracts on R and chooses c, it can never achieve $p_{hh} = 1$ and $p_{ll} = 1$, as is apparent from (1) and (2). Instead, the optimal level of conservatism, $c = e_2$, leads to $p_{ll} = 1$ and $p_{hh} < 1$, which implies that only the high report, but not the low report, is a perfect indicator of output X. Inspection of (29), (30), (40), and (41) shows that the optimal contract and actions are determined by $\frac{p_{hl}}{p_{hh}-p_{hl}}$. Since $c = e_2$ achieves $p_{hl} = 0$, the optimal earnings-based contract replicates the optimal output-based contract.

[14] We thank the referee for suggesting this discussion.

with $\delta \in \{0, 1\}$. The innovation yields a high output, $X = X_h$, if the project's type and the demand are both high, $T = T_h$ and $\delta = 1$, and a low output, $X = X_l$, otherwise.

The manager's private information θ is now the probability that the project type is high, $T = T_h$. The distribution of θ and the effect of innovation effort a is as in the main setting. The interim accounting report R is informative of the project's type T only. Specifically, equivalent to the base setting, evidence e is given by $e = T + \varepsilon$, where ε is drawn from a distribution with density $g(\varepsilon)$ and positive support over $(-L, L)$. Any evidence e below $e_1 = T_h - L$ indicates a low project type; any evidence above $e_2 = T_l + L$ indicates a high type; and evidence in the range (e_1, e_2) is inconclusive about T. The likelihood ratio $g(e|T_h)/g(e|T_l)$ is non-decreasing in e for all $e \in [e_1, e_2]$, that is, the MLRP holds. As in the main setting, the degree of conservatism c partitions the evidence into a high and low report. When c increases, the high report R_h becomes a more accurate indicator that the project type is high, $T = T_h$, for all $c \in [e_1, e_2)$ and R_h is a perfect indicator of $T = T_h$ if $c = e_2$.

After choosing effort a but before making the investment decision, the manager learns the realizations of θ and δ. Given θ and δ, the new project generates the high output X_h with probability $\delta\theta$ and the low output X_l with probability $(1 - \delta\theta)$. The first-best investment decision is to invest if and only if $\delta = 1$ and $\theta \geq \theta_{FB}$. Assuming the ex ante probability of a high demand $(\delta = 1)$ is $\pi \in (0, 1)$, the first-best effort level is $a_{FB} = \frac{\pi}{k} \int_{\theta_{FB}}^{1} (\theta X_h + (1 - \theta) X_l - X_m) f(\theta) d\theta$.

If the manager's bonus just depends on the report R, the manager will ignore the long-term demand δ and invest even when $\delta = 0$ because the report does not capture this information. Suppose, however, the contract can be based on the interim stock price, denoted P, which is the price that arises after the report R is issued but before the long-term cash flow X is realized. Further, suppose the market is informed about the innovation's long-term demand δ, so that the stock price after investment not only reflects R but also δ and is given by $P(R, \delta)$.

The optimal contract awards the manager the high bonus w_h only when the stock price exceeds the performance target $\overline{P} = P(R_h, 1)$, which is the case when the report and the demand are both high, $R = R_h$ and $\delta = 1$.[15] As before, the manager's pay is w_m when the report is R_m, indicating business as usual (or, alternatively, when the stock price is $P(R_m)$). Linking the high bonus w_h to the stock price P (rather than just the report R) ensures that the manager does not invest in the innovation when there is no long-term demand for it $(\delta = 0)$. The pay plan also has to induce the manager to exert innovation effort and to make an appropriate investment decision based on her private information θ about the project's type. Similar to the base setting, a higher degree of conservatism c is valuable because it permits the board to better tackle these two incentive problems (until $c = e_2$). This follows because the stock price meets the target $\overline{P}$ (which yields the high bonus w_h) only when the accounting report is high and a high report is a more informative indicator of the high project type when the accounting system is more conservative.[16]

7. Discussion and empirical implications

Conservative accounting practices require companies to prepare financial reports with caution and to choose reporting methods that reduce the risk of exaggerated financial statements. In our model, the optimal accounting rule ensures that if there is uncertainty, firms have to play it safe and use methods that understate, rather than overstate, financial performance. However, our model should not be interpreted as predicting that firms will adopt accounting practices that eliminate the risk of overstatements. Rather, the goal of our model is to identify one benefit of conservative accounting that has been overlooked in the literature, namely that conservatism can help encourage innovation in organizations. In practice, other forces will also influence the firm's choice of conservatism, such as the legal liability environment, the manager's ability to engage in earnings manipulation, and the firm's desire to raise debt. For example, Gigler et al. (2009) show in a debt contracting setting in which the lender receives control rights when debt covenants are violated that the optimal accounting system can be aggressive. Bertomeu et al. (2017) and Caskey and Laux (2017) show that conservative accounting practices can increase managers' incentives to engage in costly manipulation of earnings reports, which renders conservative accounting less desirable. The ultimate level of conservatism that firms will choose will balance these competing forces.

The main predictions of our model are directional. Specifically, our model suggests that adopting more conservative accounting practices will lead to (i) stronger managerial incentives to develop innovative ideas, and (ii) weaker incentives to invest in new ideas that have a negative net present value. A large empirical literature studies the effects of conservative accounting on corporate investments and finds evidence of a negative relation between conservatism and overinvestment, consistent with our model.[17]

To the best of our knowledge, the working paper by Chang et al. (2015) is the only empirical study that examines the association between conservatism and innovation in organizations. Using the number of patents and patent citations as a proxy for the level of innovation, Chang et al. (2015) find a negative relation between conservatism and innovation. They argue that managers are under pressure to meet short-term performance targets, and conservative accounting adds to this

[15] Assuming the firm has N outstanding shares of stock, the stock price $P(R_h, 1)$ is given by $E[X|R_h, 1]/N = (\Pr(X_h|R_h, 1)X_h + \Pr(X_l|R_h, 1)X_l)/N$, with $\Pr\ (X_h|R_h,\ 1) = \frac{\frac{p_{hh}}{p_{hl}}}{\frac{p_{hh}}{p_{ll}} + \frac{\int_{\theta_T}^{1}(1-\theta)f(\theta)d\theta}{\int_{\theta_T}^{1}\theta f(\theta)d\theta}}$ and $\Pr(X_l|R_h,\ 1) = 1 - \Pr(X_h|R_h,\ 1)$.

[16] Note that the stock price $\overline{P} = P(R_h, 1)$ increases in conservatism c and equals $P(R_h, 1) = X_h/N$ when $c = e_2$, where N is the number of outstanding shares.

[17] See, e.g., Francis and Martin (2010), Bushman et al. (2011), Ball and Shivakumar (2005), and Garcia Lara et al. (2016).

pressure, which causes managers to forego investments in innovation (similar to the intuition behind real earnings management). The empirical findings in Chang et al. (2015) do not contradict our theory, as the number of patents and patent citations are unlikely to capture the type of innovation we have in mind. In our model, the manager either continues with business as usual or implements an innovation. For example, a consumer electronics company can venture out into new technologies, products, and markets that depart from their existing business model (think of Apple creating the iPhone). This type of innovation changes the direction of the firm and is highly risky and disruptive. Alternatively, the firm can continue with business as usual, which will likely lead to improvements of existing products and services (think of Apple's yearly update of the iPhone). Since both types of activities generate patents, the number of patents is not a useful proxy for the type of innovation our model addresses. Balsmeier et al. (2017) have developed new, more refined measures of innovation to distinguish between exploration of new technologies and exploitation of well-known technologies. For example, they argue that patents that cite other patents owned by the same company are based on existing knowledge, while patents that do not cite other patents are more explorative. These more refined measures of innovation could be used to test our theory, and we encourage empirical researchers to do so.

8. Conclusion

Innovation and conservatism seem to be conflicting concepts: Innovation involves risk taking and discovery, while conservatism embodies caution and risk avoidance. In this paper, we argue that conservatism can nevertheless foster innovation. Our model of innovation involves a manager who must first exert costly effort to develop a viable innovation and then decide whether to implement the innovation based on private information about its success probability. Due to the long-term nature of innovation, the manager is paid based on an interim accounting report that is informative about the economic performance of the firm.

We first discuss the effects of conservative accounting on managerial behavior, assuming that the manager's pay plan is exogenously fixed. More conservatism reduces the probability that risky investments yield high earnings reports, and therefore weakens the manager's incentive to spend effort working on new ideas ex ante. Further, conservatism increases the profitability threshold above which the manager invests in a new idea, which either increases or decreases investment efficiency, depending on whether the manager is initially tempted to overinvest or underinvest in the innovation. The effect of conservatism on firm value is therefore ambiguous. These findings are broadly consistent with informal arguments in the literature.

Corporate boards, however, design optimal incentive pay plans, and these plans change when the accounting system changes. When designing the optimal contract, the board faces the challenge of providing the manager with incentives to spend effort on innovative ideas without inducing her to subsequently overinvest in a new idea. We find that conservative accounting allows the board to link the manager's compensation more closely to the performance of the innovation, which alleviates the tension between inducing innovation effort and inducing efficient investment, and hence leads to more efficient actions. As a result, in equilibrium, more conservative accounting (i) increases the manager's incentive to work on innovative ideas, (ii) reduces her incentive to overinvest in an innovation, and (iii) increases firm value. These results stand in contrast to the standard arguments offered in the literature.

Our model highlights the dangers of evaluating changes in accounting practices in isolation from other governance instruments. Boards have multiple tools to control managerial behavior, and one important tool is incentive contracting. Although conservatism impedes innovation when all else is held constant, we find that this result flips when one takes into account that incentive contracts are optimally adjusted in response to changes in the reporting environment. This demonstrates that changes in accounting practices should not be evaluated in a vacuum, but in conjunction with other governance tools.

Appendix A. Verifiable Profitability

In this appendix, we consider the case in which the manager's information θ is observable and verifiable so that the report R can be based on θ. Consider the following reporting system. If the project is implemented, the report is high, $R = R_h$, if $\theta \geq c$, and low, $R = R_l$, if $\theta < c$. If the firm continues the status quo, the report is R_m. The optimal contract awards the manager a bonus $w_h > 0$ when the report is high, $R = R_h$, and pays her zero otherwise, that is, $w_l = w_m = 0$. The optimal value of c is any value that satisfies $c \geq \theta_{FB}$.

This pay plan induces the manager to spend innovation effort without encouraging her to overinvest in the innovation. That is, the goal of inducing effort does not interfere with the goal of inducing efficient investment (which stands in contrast to the main model where θ is not observable). To see why the manager makes the desired investment decision note that for all $\theta \geq c$, the manager prefers to invest in the project to obtain w_h, which is efficient since $c \geq \theta_{FB}$. For all $\theta < c$, the manager is indifferent between implementing the innovation and continuing the status quo (because in both cases she obtains zero). Assuming the manager behaves in the best interest of the firm when indifferent, she will implement the project if and only if $\theta \geq \theta_{FB}$.

The only remaining incentive problem is to provide the manager with incentives to work on the innovation. Given w_h, the manager's effort choice is

$$a = \int_c^1 w_h f(\theta)d\theta/k. \tag{19}$$

The board's goal is to maximize the expected cash flows minus the manager's expected pay

$$a\left(\int_{\theta_{FB}}^1 (\theta X_h + (1-\theta)X_l)f(\theta)d\theta + F(\theta_{FB})X_m\right) + (1-a)X_m - a\int_c^1 w_h f(\theta)d\theta. \tag{20}$$

Substituting (19) into (20) and taking the first-order condition with respect to a yields

$$\left(\int_{\theta_{FB}}^1 (\theta X_h + (1-\theta)X_l)f(\theta)d\theta + F(\theta_{FB})X_m\right) - X_m - 2ka = 0, \tag{21}$$

which determines the optimal innovation effort, denoted $a^{\#}$. Using (15), equation (21) simplifies to $a^{\#} = 0.5a_{FB}$. The optimal pay w_h is then $w_h = ka^{\#}/(\int_c^1 f(\theta)d\theta)$, the manager's expected pay is $a^{\#}\int_c^1 w_h f(\theta)d\theta = k(a^{\#})^2$, and the value of the firm is

$$a^{\#}\left(\int_{\theta_{FB}}^1 (\theta X_h + (1-\theta)X_l)f(\theta)d\theta + F(\theta_T)X_m - X_m\right) + X_m - k(a^{\#})^2.$$

Two observations are useful. First, the board implements the first-best investment decision but not first-best effort. When the board induces a certain effort level a, the manager receives an expected compensation of $V = ka^2$, but the actual effort cost is $0.5ka^2$, leaving the manager with a utility of $V - 0.5ka^2 = 0.5ka^2$. To economize on the manager's rents, the board induces an innovation effort level that lies below first-best, that is, $a^{\#} = 0.5a_{FB}$.

Second, the level of conservatism c plays no role as long as $c \geq \theta_{FB}$. Thus, any $c \geq \theta_{FB}$ constitutes an optimal reporting system. The intuition for this finding is as follows. When the degree of conservatism c increases, the manager is less likely to receive the bonus w_h, which reduces her effort incentive (as is apparent from (19)). To restore effort incentives, the board has to offer a higher bonus w_h. The increase in w_h perfectly offsets the effect of an increase in c such that the expected pay to the manager remains unchanged. As a result, the cost of inducing innovation effort a is independent from c.

Appendix B. Communication

In this appendix, we consider a direct revelation mechanism, in which the investment decision and payments to the manager are contingent on the manager's message $\widehat{\theta}$. After the manager exerts effort a, she learns $\theta \in [0,1]$. At the beginning of the game, the board commits to a menu of contracts $M = (I(\widehat{\theta}), w_h(\widehat{\theta}), w_l(\widehat{\theta}), w_m(\widehat{\theta}))$. By sending a message $\widehat{\theta}$, the manager selects a contract from the menu. The parameter $I(\widehat{\theta}) \in \{0,1\}$ is an indicator variable that denotes whether the new investment idea is pursued. If $I = 1$, the project is implemented and if $I = 0$, the project is rejected. $w_h(\widehat{\theta})$ or $w_l(\widehat{\theta})$ are the payments to the manager if the project is implemented and the accounting report is high R_h or low R_l, respectively. $w_m(\widehat{\theta})$ is the pay if the project is rejected. By the revelation principle, we can restrict attention to contracts that induce the manager to truthfully reveal her private information. In the optimal mechanism, for any two messages $\widehat{\theta}_i$ and $\widehat{\theta}_j$ for which the board rejects the project, $I(\widehat{\theta}_i) = I(\widehat{\theta}_j) = 0$, the manager must receive the same pay $w_m(\widehat{\theta}_i) = w_m(\widehat{\theta}_j) \geq 0$. Otherwise, if $w_m(\widehat{\theta}_i) > w_m(\widehat{\theta}_j)$ and $I(\widehat{\theta}_i) = I(\widehat{\theta}_j) = 0$, the manager would announce $\widehat{\theta}_i$ even when $\widehat{\theta}_j$ is true. Equivalently, since the optimal contract does not reward the manager for poor performance, $w_l = 0$, the manager must receive $w_h(\widehat{\theta}_i) = w_h(\widehat{\theta}_j)$ for all $\widehat{\theta}_i, \widehat{\theta}_j$ for which $I(\widehat{\theta}_i) = I(\widehat{\theta}_j) = 1$.

Further, the optimal mechanism involves a cutoff θ_T such that $I = 0$ if $\widehat{\theta} \in [0, \theta_T)$ and $I = 1$ if $\widehat{\theta} \in [\theta_T, 1]$. This follows because if $I(\widehat{\theta}_i) = 1$, then it must be that $I(\widehat{\theta}_j) = 1$ for all $\widehat{\theta}_j > \widehat{\theta}_i$. Suppose to the contrary that $I(\widehat{\theta}_i) = 1$, $I(\widehat{\theta}_j) = 0$, and $\widehat{\theta}_j > \widehat{\theta}_i$. The incentive compatibility for truthtelling requires that $(\theta_i p_{hh} + (1-\theta_i)p_{hl})w_h \geq w_m$ and $w_m \geq (\theta_j p_{hh} + (1-\theta_j)p_{hl})w_h$. If the first condition is satisfied, the second is violated and vice versa, since $\theta_j > \theta_i$ and $p_{hh} > p_{hl}$.

As a consequence, the mechanism M can be replicated by the simple contract (w_h, w_m, w_l), in which payments are independent of the manager's message $\widehat{\theta}$ and the manager makes the investment decision (rather than sending a message that determines the investment decision).

Appendix C. Properties of Conservatism

We prove that the conditional probabilities in (1) and (2) imply properties (A1) to (A3). Rewriting the conditional probability p_{hl} from (1) as $p_{hl} = \int_{c+X_h-X_l}^{X_h+L} g(e|X_h)de$ and the conditional probability p_{ll} from (2) as $p_{ll} = \int_{X_h-L}^{c+X_h-X_l} g(e|X_h)de$ shows that

$$p_{hh} = \int_c^{X_h+L} g(e|X_h)de > p_{hl}$$

and

$$p_{ll} > p_{lh} = \int_{X_h-L}^{c} g(e|X_h)de,$$

implying (A1).
Taking the first derivatives of the conditional probabilities in (1) and (2) yields $\frac{dp_{lh}}{dc} = g(e|X_h) > 0$ and $\frac{dp_{ll}}{dc} = g(e|X_l) > 0$, implying (A2).

Finally, using (1) and (2), we obtain

$$\frac{d\frac{p_{hh}}{p_{hl}}}{dc} = \frac{-g(c|X_h)}{\int_c^{X_l+L} g(e|X_l)de} + g(c|X_l)\frac{\int_c^{X_h+L} g(e|X_h)de}{\left(\int_c^{X_l+L} g(e|X_l)de\right)^2}$$

$$= \frac{\int_c^{X_l+L}\left(g(c|X_l)\left(\frac{g(e|X_h)}{g(e|X_l)} - \frac{g(c|X_h)}{g(c|X_l)}\right)g(e|X_l)\right)de + g(c|X_l)\int_{X_l+L}^{X_h+L} g(e|X_h)de}{\left(\int_c^{X_l+L} g(e|X_l)de\right)^2}.$$

Due to the MLRP ($d\frac{g(e|X_h)}{g(e|X_l)}/de \geq 0$ for $e \in [e_1, e_2]$) and due to $c < X_l + L$, the term $\int_c^{X_l+L} g(c|X_l)\left(\frac{g(e|X_h)}{g(e|X_l)} - \frac{g(c|X_h)}{g(c|X_l)}\right)g(e|X_l)de$ is nonnegative. Hence, $d\frac{p_{hh}}{p_{hl}}/dc > 0$. The Proof that $d\frac{p_{lh}}{p_{ll}}/dc > 0$ is equivalent and hence is omitted. This establishes (A3).

Appendix D. Proofs

Proof of Proposition 1. Combine (4) and (5) with (8) to get

$$\theta_T p_{hh} + (1-\theta_T)p_{hl} = \frac{w_m - w_l}{w_h - w_l}. \tag{22}$$

Using the implicit function theorem generates

$$\frac{d\theta_T}{dc} = -\frac{\theta_T\frac{dp_{hh}}{dc} + (1-\theta_T)\frac{dp_{hl}}{dc}}{p_{hh} - p_{hl}} > 0, \tag{23}$$

which is positive since $\frac{dp_{hh}}{dc} < 0$ and $\frac{dp_{hl}}{dc} < 0$ from condition (A2).

Using (11), we obtain

$$\frac{da}{dc} = -\frac{1}{k}(\theta_T E[w|X_h] + (1-\theta_T)E[w|X_l] - w_m)f(\theta_T)\frac{d\theta_T}{dc} + \frac{(w_h - w_l)}{k}\int_{\theta_T}^{1}\left(\theta\frac{dp_{hh}}{dc} - (1-\theta)\frac{dp_{ll}}{dc}\right)f(\theta)d\theta < 0. \tag{24}$$

The first line in (24) is zero since the manager's optimal choice of θ_T solves (8), and the second line in (24) is negative since $\frac{dp_{hh}}{dc} < 0$ and $\frac{dp_{ll}}{dc} > 0$ from (A2).

Using (4) and (5), we can write (10) as

$$\Psi = a\int_{\theta_T}^{1}(\theta(p_{hh}w_h + p_{lh}w_l) + (1-\theta)(p_{hl}w_h + p_{ll}w_l) - w_m)f(\theta)d\theta + w_m. \tag{25}$$

Taking the first derivative with respect to c yields

$$\begin{aligned}\frac{d\Psi}{dc} = & \frac{da}{dc}\int_{\theta_T}^{1}(\theta(p_{hh}w_h + p_{lh}w_l) + (1-\theta)(p_{hl}w_h + p_{ll}w_l) - w_m)f(\theta)d\theta \\ & - a(\theta_T(p_{hh}w_h + p_{lh}w_l) + (1-\theta_T)(p_{hl}w_h + p_{ll}w_l) - w_m)f(\theta_T)\frac{d\theta_T}{dc} \\ & + a(w_h - w_l)\int_{\theta_T}^{1}\left(\theta\frac{dp_{hh}}{dc} + (1-\theta)\frac{dp_{hl}}{dc}\right)f(\theta)d\theta.\end{aligned} \tag{26}$$

The second line in (26) is zero from equation (8). The first line is negative since we just established that $\frac{da}{dc} < 0$, and the third line is negative since $\frac{dp_{hh}}{dc} < 0$ and $\frac{dp_{hl}}{dc} < 0$ from (A2). Using (11), we can simplify (26) to

$$\frac{d\Psi}{dc} = \frac{da}{dc}ka + a(w_h - w_l)\int_{\theta_T}^{1}\left(\theta\frac{dp_{hh}}{dc} + (1-\theta)\frac{dp_{hl}}{dc}\right)f(\theta)d\theta, \tag{27}$$

and using (24), we obtain

$$\frac{d\Psi}{dc} = 2\frac{da}{dc}ka < 0. \tag{28}$$

Proof of Proposition 2. To determine the equilibrium actions, we proceed in two steps. In the first, we specify the least costly contract that implements a certain effort level and investment threshold combination (a, θ_T). In the second step, we solve for the optimal (a^*, θ_T^*) combination, given that the board will choose the least expensive contract for any (a, θ_T). The next lemma presents the results from the first step.

Lemma 1. *Let $\{w_i^*(\theta_T, a)\}_{i=h,m,l}$ denote the least costly contract that elicits innovation effort a and the investment threshold θ_T. Then,*

$$w_h^*(\theta_T, a) = \frac{ak}{(p_{hh} - p_{hl})\left(\int_{\theta_T}^{1}(\theta - \theta_T)f(\theta)d\theta\right)}, \tag{29}$$

$$w_m^*(\theta_T, a) = (\theta_T p_{hh} + (1-\theta_T)p_{hl})w_h^* \text{ and } w_l^*(\theta_T, a) = 0, \tag{30}$$

and the expected compensation $\Psi(\theta_T, a)$ and the manager's utility $U(\theta_T, a)$ are

$$\Psi(\theta_T, a) = ka^2 + w_m^*(\theta_T, a), \tag{31}$$

$$U(\theta_T, a) = 0.5ka^2 + w_m^*(\theta_T, a). \tag{32}$$

Proof: The pay w_m is determined by the investment condition (8), and is given by

$$w_m = \theta_T E[w|X_h] + (1-\theta_T)E[w|X_l]. \tag{33}$$

Substituting (33) into the effort constraint (11) yields

$$a = \frac{1}{k}\int_{\theta_T}^{1}(\theta - \theta_T)(E[w|X_h] - E[w|X_l])f(\theta)d\theta. \tag{34}$$

After inserting (4) and (5) into (34) and rearranging, we obtain

$$(w_h - w_l) = \frac{ak}{(p_{hh} - p_{hl})\int_{\theta_T}^{1}(\theta - \theta_T)f(\theta)d\theta}. \tag{35}$$

Substituting (35) into (33) yields

$$w_m = \frac{\theta_T + \frac{p_{hl}}{p_{hh} - p_{hl}}}{\left(\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta \right)} ak + w_l. \tag{36}$$

Substituting (11) and (36) into (10) yields the manager's expected compensation when the board implements (a, θ_T)

$$\Psi = a^2 k + \frac{\theta_T + \frac{p_{hl}}{p_{hh} - p_{hl}}}{\left(\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta \right)} ak + w_l. \tag{37}$$

From (37) it immediately follows that $w_l = 0$ is optimal (given the limited liability constraint $w_l \geq 0$). Using (36) and setting $w_l = 0$, we obtain (31).

Step 2: Substituting (31) into the board's utility function (13), we can write the board's problem as

$$\max_{a, \theta_T, w_l} V \equiv a \left(\int_{\theta_T}^{1} (\theta X_h + (1-\theta) X_l) f(\theta) d\theta + F(\theta_T) X_m \right) + (1-a) X_m \tag{38}$$

$$- \left(ka^2 + \frac{\theta_T + \frac{p_{hl}}{p_{hh} - p_{hl}}}{\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta} ka \right),$$

subject to the manager's participation constraint

$$U = 0.5ka^2 + \frac{\theta_T + \frac{p_{hl}}{p_{hh} - p_{hl}}}{\left(\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta \right)} ka \geq \underline{U}. \tag{39}$$

As discussed in Section 2, the limited liability constraints imply that the board has to rely on rewards to provide incentives (and cannot use punishments), which yields the manager a positive utility. If the manager's reservation utility is not larger than a certain threshold, denoted $\underline{U}_T$, she enjoys an economic rent, that is, the participation constraint is slack. In what follows, we assume that this is the case and determine $\underline{U}_T$ below.

Taking the first-order conditions for θ_T and a yields

$$\frac{\partial V}{\partial \theta_T} = -(\theta_T X_h + (1-\theta_T) X_l - X_m) f(\theta_T) \tag{40}$$

$$- \frac{k}{\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta} \left(1 + \int_{\theta_T}^{1} f(\theta) d\theta \frac{\theta_T + \frac{p_{hl}}{(p_{hh} - p_{hl})}}{\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta} \right) = 0,$$

and

$$\frac{\partial V}{\partial a} = \int_{\theta_T}^{1} (\theta X_h + (1-\theta) X_l - X_m) f(\theta) d\theta \tag{41}$$

$$- \left(2a + \frac{\theta_T + \frac{p_{hl}}{(p_{hh} - p_{hl})}}{\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta} \right) k = 0.$$

Since $\theta_{FB}X_h + (1-\theta_{FB})X_l = X_m$ by definition, equation (40) implies $\theta_T^* < \theta_{FB}$. Equation (41) implies

$$a^* = 0.5\left(\frac{1}{k}\int_{\theta_T^*}^{1}(\theta X_h + (1-\theta)X_l - X_m)f(\theta)d\theta - \frac{\theta_T^* + \frac{p_{hl}}{p_{hh}-p_{hl}}}{\int_{\theta_T^*}^{1}(\theta-\theta_T^*)f(\theta)d\theta}\right), \tag{42}$$

where (a^*, θ_T^*) are the optimal actions. Using

$$a_{FB} = \frac{1}{k}\int_{\theta_{FB}}^{1}(\theta X_h + (1-\theta)X_l - X_m)f(\theta)d\theta,$$

we obtain

$$a^* = 0.5\left(a_{FB} + \frac{1}{k}\int_{\theta_T^*}^{\theta_{FB}}(\theta X_h + (1-\theta)X_l - X_m)f(\theta)d\theta - \frac{\theta_T + \frac{p_{hl}}{p_{hh}-p_{hl}}}{\int_{\theta_T^*}^{1}(\theta-\theta_T^*)f(\theta)d\theta}\right). \tag{43}$$

Since $(\int_{\theta_T^*}^{\theta_{FB}}(\theta X_h + (1-\theta)X_l - X_m)f(\theta)d\theta) < 0$, it follows that $a^* < 0.5a_{FB}$. The result that $a^* < 0.5a_{FB}$ is an artifact of the quadratic effort cost function, the limited liability assumption, and the fact that the board has to deal with the dual problems of inducing effort and inducing efficient investment.

The second-order conditions for a maximum are satisfied if

$$\frac{\partial^2 V}{\partial\theta_T^2}\frac{\partial^2 V}{\partial a^2} - \left(\frac{\partial^2 V}{\partial\theta_T\partial a}\right)^2 > 0, \tag{44}$$

$$\frac{\partial^2 V}{\partial a^2} < 0, \tag{45}$$

where $\frac{\partial^2 V}{\partial\theta_T\partial a} = 0$, $\frac{\partial^2 V}{\partial a^2} = -2k$ and

$$\begin{aligned}\frac{\partial^2 V}{\partial\theta_T^2} = &-(X_h - X_l)f(\theta_T) - (\theta_T X_h + (1-\theta_T)X_l - X_M)\frac{df(\theta_T)}{d\theta_T}\\ &-\frac{k\left(\theta_T + \frac{p_{hl}}{p_{hh}-p_{hl}}\right)}{\left(\int_{\theta_T}^{1}(\theta-\theta_T)f(\theta)d\theta\right)^2}\left[\frac{2\left(\int_{\theta_T}^{1}f(\theta)d\theta\right)^2 - f(\theta_T)\int_{\theta_T}^{1}(\theta-\theta_T)f(\theta)d\theta}{\int_{\theta_T}^{1}(\theta-\theta_T)f(\theta)d\theta}\right]\\ &-\frac{2k\int_{\theta_T}^{1}f(\theta)d\theta}{\left(\int_{\theta_T}^{1}(\theta-\theta_T)f(\theta)d\theta\right)^2}.\end{aligned} \tag{46}$$

Conditions (44) and (45) are therefore satisfied when $\frac{\partial^2 V}{\partial\theta_T^2} < 0$. We obtain $\frac{\partial^2 V}{\partial\theta_T^2} < 0$, for example, when the marginal cost of effort, k, is sufficiently high, because the term in square brackets in (46) is positive.

Using (39), the manager's participation constraint is indeed slack (as initially assumed) when her reservation utility $\underline{U}$ is not larger than

$$\underline{U}_T \equiv 0.5ka^{*2} + \frac{\theta_T^* + \frac{p_{hl}}{p_{hh}-p_{hl}}}{\int_{\theta_T^*}^{1}(\theta-\theta_T^*)f(\theta)d\theta}ka^*,$$

where θ_T^* and a^* are determined by the first-order conditions (40) and (41). Substituting (41) into $\underline{U}_T$ yields

$$\underline{U}_T = \left(a^* \int_{\theta_T^*}^{1} (\theta X_h + (1-\theta)X_l - X_m) f(\theta) d\theta - 0.5ka^{*2} \right) - ka^{*2}. \tag{47}$$

The term in parentheses in (47) is the total surplus associated with innovation effort, that is, the increase in expected cash flows from the manager's innovation effort a^* minus her personal cost of effort.

Proof of Proposition 3. We first show that an increase in c and w_h allows the board to increase the manager's incentive to work on the innovation without increasing her incentive to overinvest in the innovation; that is, a increases but θ_T remains unchanged. Solving the investment constraint (8) for w_h and setting $w_l = 0$ yields

$$w_h(\theta_T) = \frac{w_m}{(\theta_T p_{hh} + (1-\theta_T) p_{hl})}.$$

As c increases, the bonus $w_h(\theta_T)$ must increase to maintain the investment threshold θ_T. Inserting $w_h(\theta_T)$ into the effort constraint (11) and setting $w_l = 0$ yields, after some rearranging,

$$a = \frac{1}{k} \int_{\theta_T}^{1} \left(\frac{\theta \frac{p_{hh}}{p_{hl}} + (1-\theta)}{\theta_T \frac{p_{hh}}{p_{hl}} + (1-\theta_T)} - 1 \right) w_m f(\theta) d\theta.$$

Taking the first derivative shows that an increase in c increases the effort level a:

$$\frac{da}{dc} = \frac{d\frac{p_{hh}}{p_{hl}}}{dc} \frac{\int_{\theta_T}^{1} (\theta - \theta_T) f(\theta) d\theta}{k\left(\theta_T \frac{p_{hh}}{p_{hl}} + (1-\theta_T)\right)^2} w_m > 0,$$

since $\frac{d\frac{p_{hh}}{p_{hl}}}{dc} > 0$. Thus, an increase in c (and the subsequent increase in w_h that is required to keep the investment threshold θ_T unchanged) increases the manager's incentive to work on the innovation.

Alternatively, the board can increase c and w_h to reduce the manager's incentive to overinvest in the innovation without reducing her effort incentive; that is, θ_T increases but a remains unchanged. Solving effort constraint (11) for w_h and setting $w_l = 0$ yields

$$w_h(a) = \frac{ka + w_m \int_{\theta_T}^{1} f(\theta) d\theta}{\int_{\theta_T}^{1} (\theta p_{hh} + (1-\theta) p_{hl}) f(\theta) d\theta}. \tag{48}$$

Note that as c increases, the bonus $w_h(a)$ must increase to maintain the effort level a. Substituting (48) into the investment constraint (8) with $\Pr(X_h|R_h, 1) = \frac{\frac{p_{hh}}{p_{hl}}}{\frac{p_{hh}}{p_{hl}} + \frac{\int_{\theta_T^*}^{1} (1-\theta) f(\theta) d\theta}{\int_{\theta_T^*}^{1} \theta f(\theta) d\theta}}$ and rearranging yields

$$Q \equiv \left(\theta_T \frac{p_{hh}}{p_{hl}} + (1-\theta_T) \right) \frac{ka + w_m \int_{\theta_T}^{1} f(\theta) d\theta}{\int_{\theta_T}^{1} \left(\theta \frac{p_{hh}}{p_{hl}} + (1-\theta) \right) f(\theta) d\theta} - w_m = 0. \tag{49}$$

Using the implicit function theorem, we obtain

$$\frac{d\theta_T}{dc} = -\frac{dQ/dc}{dQ/d\theta_T},$$

where

$$\frac{dQ}{dc} = -\frac{\left(ka + w_m\int_{\theta_T}^{1} f(\theta)d\theta\right)\left(\int_{\theta_T}^{1}(\theta-\theta_T)f(\theta)d\theta\right)}{\left(\int_{\theta_T}^{1}\left(\theta\frac{p_{hh}}{p_{hl}} + (1-\theta)\right)f(\theta)d\theta\right)^2}\frac{d\frac{p_{hh}}{p_{hl}}}{dc} < 0,$$

and

$$\frac{dQ}{d\theta_T} = \left(\frac{p_{hh}}{p_{hl}} - 1\right)\frac{ka + w_m\int_{\theta_T}^{1} f(\theta)d\theta}{\int_{\theta_T}^{1}\left(\theta\frac{p_{hh}}{p_{hl}} + (1-\theta)\right)f(\theta)d\theta}$$

$$+\left(\theta_T\frac{p_{hh}}{p_{hl}} + (1-\theta_T)\right)f(\theta_T)\frac{\left(\theta_T\frac{p_{hh}}{p_{hl}} + (1-\theta_T)\right)\left(ka + w_m\int_{\theta_T}^{1} f(\theta)d\theta\right)}{\left(\int_{\theta_T}^{1}\left(\theta\frac{p_{hh}}{p_{hl}} + (1-\theta)\right)f(\theta)d\theta\right)^2}$$

$$+\left(\theta_T\frac{p_{hh}}{p_{hl}} + (1-\theta_T)\right)\frac{-w_m f(\theta_T)}{\int_{\theta_T}^{1}\left(\theta\frac{p_{hh}}{p_{hl}} + (1-\theta)\right)f(\theta)d\theta},$$

which using (49) simplifies to

$$\frac{dQ}{d\theta_T} = \left(\frac{p_{hh}}{p_{hl}} - 1\right)\frac{ka + w_m\int_{\theta_T}^{1} f(\theta)d\theta}{\int_{\theta_T}^{1}\left(\theta\frac{p_{hh}}{p_{hl}} + (1-\theta)\right)f(\theta)d\theta} > 0.$$

These calculations show that $\frac{d\theta_T}{dc} > 0$, implying that an increase in c (and the subsequent increase in w_h required to preserve effort incentives) increases the manager's investment threshold θ_T.

Proof of Proposition 4. Differentiating the first-order condition (40) with respect to c yields

$$\frac{\partial^2 V}{\partial\theta_T^2}\frac{\partial\theta_T^*}{\partial c} + \frac{\partial^2 V}{\partial\theta_T\partial a}\frac{\partial a^*}{\partial c} + \frac{\partial^2 V}{\partial\theta_T\partial c} = 0,$$

where $\frac{\partial^2 V}{\partial\theta_T\partial a} = 0$ and

$$\frac{\partial^2 V}{\partial\theta_T\partial c} = \frac{\frac{d\frac{p_{hh}}{p_{hl}}}{dc}\int_{\theta_T}^{1} f(\theta)d\theta}{\left(\frac{p_{hh}}{p_{hl}} - 1\right)^2\left(\int_{\theta_T}^{1}(\theta-\theta_T)f(\theta)d\theta\right)^2}k > 0, \tag{50}$$

which is positive because $d\frac{p_{hh}}{p_{hl}}/dc > 0$ from (A3) and $\frac{p_{hh}}{p_{hl}} > 1$ from (A1). Further, $\frac{\partial^2 V}{\partial\theta_T^2} < 0$ by the second-order condition for a maximum.

Differentiating the first-order condition (41) with respect to c yields:

$$\frac{\partial^2 V}{\partial a^2}\frac{\partial a^*}{\partial c} + \frac{\partial^2 V}{\partial a\partial\theta_T}\frac{\partial\theta_T^*}{\partial c} + \frac{\partial^2 V}{\partial a\partial c} = 0,$$

where

$$\frac{\partial^2 V}{\partial a^2} = -2k, \quad \frac{\partial^2 V}{\partial a \partial c} = \frac{\frac{d\frac{p_{hh}}{p_{hl}}}{dc}k}{\left(\frac{p_{hh}}{p_{hl}} - 1\right)^2 \int_{\theta_T}^1 (\theta - \theta_T) f(\theta) d\theta} > 0, \text{ and } \frac{\partial^2 V}{\partial a \partial \theta_T} = 0.$$

Since $d\frac{p_{hh}}{p_{hl}}/dc > 0$ from (A3) and $\frac{p_{hh}}{p_{hl}} > 1$ from (A1), $\frac{\partial^2 V}{\partial a \partial c} > 0$. We therefore obtain

$$\frac{\partial \theta_T^*}{\partial c} = -\frac{\frac{\partial^2 V}{\partial \theta_T \partial c}}{\frac{\partial^2 V}{\partial \theta_T^2}} > 0 \text{ and } \frac{\partial a^*}{\partial c} = -\frac{\frac{\partial^2 V}{\partial a \partial c}}{\frac{\partial^2 V}{\partial a^2}} > 0.$$

In the optimal solution, firm value is

$$V(a, \theta_T, c) = CF(a, \theta_T) - \Psi(a, \theta_T, c), \tag{51}$$

where the levels of a and θ_T satisfy the first-order conditions (40) and (41). The expected cash flow CF is given in (12). From Proposition 1, the expected compensation is

$$\Psi(\theta_T, a, c) = ka^2 + \frac{\left(\theta_T + \frac{p_{hl}}{p_{hh} - p_{hl}}\right) ak}{\int_{\theta_T}^1 (\theta - \theta_T) f(\theta) d\theta}.$$

By the envelope theorem,

$$\frac{dV(c)}{dc} = \left.\frac{\partial V(\theta_T, a, c)}{\partial c}\right|_{\substack{\theta_T = \theta_T^*(c) \\ a = a^*(c)}} \tag{52}$$

where $\theta_T^*(c)$ and $a^*(c)$ are the optimal solutions for any given c. We now obtain

$$\frac{dV(c)}{dc} = -\left.\frac{\partial \Psi(\theta_T, a, c)}{\partial c}\right|_{\substack{\theta_T = \theta_T^*(c) \\ a = a^*(c)}} > 0, \tag{53}$$

where

$$\frac{\partial \Psi(\theta_T, a, c)}{\partial c} = -\frac{d\frac{p_{hh}}{p_{hl}}}{dc} \frac{ak}{\left(\frac{p_{hh}}{p_{hl}} - 1\right)^2 \int_{\theta_T}^1 (\theta - \theta_T) f(\theta) d\theta}$$

is negative since $d\frac{p_{hh}}{p_{hl}}/dc > 0$ from (A3).

Abstract

Purpose – This study aims to identify the impact of corporate governance on performance of sugar mills. In order to study this relation, a model is constructed in which ownership structure and independent directors are taken as independent variables. Whereas firm performance is analyzed by using proxy variables such as return on asset (ROA), return on equity (ROE) and sales growth. Moreover, size of board, working capital management (WCM) and philanthropy are taken as mediating variables between governance variables and firm performance.

Design/methodology/approach – The data of 32 sugar mills listed at Pakistan Stock Exchange for the period of four years (i.e. 2014–2017) is used for this research. Moreover, to investigate the model, generalized least squares statistical method is used to measure the relationship between variables.

Findings – The results revealed that there is significant but positive relationship between independent directors and ROA while ownership structure and ROE have significant but negative relationship. Thus, the board of directors should make it sure that all stakeholders and organizations should increase the nonfamily ownership in firms for better corporate performance. Moreover, philanthropy and WCM mediate the relationship between corporate governance and firms' performance.

Practical/implications – This research work will be helpful in the corporate governance, and further researchers can conduct their study by considering executive/nonexecutive director and institutional owners as governance variables.

Originality/value – This paper fulfills an identified need to study how Corporate Governance effect the performance of firm.

Keywords Corporate governance, Firm's performance, ROA, ROE, Stakeholder, Ownership, Philanthropy

1. Introduction

The corporate sector and Institute of Chartered Accountant of Pakistan (ICAP) [1] are the main controlling bodies of capital market secretarial profession of Pakistan. Securities and Exchange Commission of Pakistan (SECP) [2] is responsible for the monitoring of the profession. International Financial Reporting Standards (IFRS) [3] foundation declares statements, which are used to take help in case of other requirements related to the economic reportage. In 2002, there were major frauds in WorldCom and Enron after that Sarbanes–Oxley act was issued; therefore, a code of conduct regarding the corporate governance (CG) system in Pakistan was introduced by SECP and that code was mentioned compulsory to be adopted within the same year 2002. Later on review of code was taken and revision of the code took place during 2012.

Shareholders/investors always try to get information that can be helpful for them to earn as much return as they can. For that purpose an effective CG system has a vital importance and current issue of discussion in business management. Many studies gained fame in the recent years by studying impact of CG on firms' performance (Sami *et al.*, 2011; Ammanna *et al.*, 2011; Stefanescu, 2011; Garcia-Meca and Ballesta, 2011; Lam and Lee, 2012; Sheikh and Wang, 2012; Ujaunwa, 2012; Rashid and Islam, 2013; Kumar and Singh, 2013). CG can be counted among the most effecting aspects of firm' governance; this area is studied at a large scale to get best firm performance. A common mind-set is that the better the CG, better will be the firm performance. CG consists of different areas such as ownership structure, board size, Chief Executive Officer (CEO) compensation, CEO duality, audit committee and ratio of board conferences and so on. These areas are studied by (Bhagat and Black, 1999; Ali and Mohtasham, 2011; Yasser *et al.*, 2011), but they do not find similar results. There are some researchers (Maury, 2006; Rashid *et al.*, 2010; Ali and Mohtasham, 2011) who conducted their studies and found a positive impact of independent board upon the firm performance, whereas others such as Bhagat and Black (1999) concluded that there is no relationship between both variables. We can define the concept of CG with several definitions. CG is defined by Gompers *et al.* (2003) with respect to investor's perspective as "both the guarantee to reimburse a reasonable profit for capital investment and the dedication to run a firm". Corporate governance directly affects the firm performance and ability of firm to access the capital market. Furthermore, the researcher advocated that level of CG of a firm could be helpful in emerging market with minor organizations as it supports to differentiate among firms. CG is a proper set of processes applied in favor of economic agents and urging them to take part in productive process within the social entity (Maati, 1999).

CG is the mechanism approved by the members of the board and its associated committees. The corporations in CG are administrated to ensure that manager runs the organization for the advantages of its stakeholders such as shareholders, creditors, suppliers and employees (Martynova and Renneboog, 2006). The basic principle of CG is the distribution of authority within a corporate, among its stockholders and the members of the board (Brown and Casey, 2012). Cadbury (2000) concluded that the aim and purpose of CG are promoting contest and permitting options to the customers for making a choice and satisfying interest of individuals, corporations and securities, respectively. Shleifer and Vishny (1997) studied that the CG is administered by board members and is implemented and evaluated through various processes within the organizations. The inside directors residing in the corporation are managers of the organization, they are well aware of the company than outside directors and they make improved decisions. The outside independent directors have less value as compared to the inside directors. The outsiders are part-timers and they do not have inside information. Most of the public and private decision-makers prefer the system of independent board (Gordon, 2006). Independent directors are assumed to be custodians of the investors' interests. Moreover, they are effective in the composition of board. Hermalin and Weisbach (1991) explained that the Board of Directors (BODs) have basic responsibility of monitoring the firms and success of board depends on the majority of independent outside directors. According to the Wall Street Journal, independent outsiders made up of 66% of all boards and 72% percent of Standard & Poor's board. The larger number of directors on the board raises the difficulty of decision-making and coordination (Cheng, 2008) but leads to its benefit to better monitoring capability, improvement in organization's capacity to perform better exterior associations (Coles *et al.*, 2008). A lot of researchers discover an insignificant association between board size and organizational performance (Ghosh, 2007). Erickson (2005) describes that there are two things that are greatly affected by board size; one is difficulty of decision-making and second is effectiveness. The board has chief tasks such as planning and execution of strategy and promoting relationships between the organization and its outer environment (Ruigrok *et al.*, 2006). According to Brennan (2006), board of corporations is essential component of CG because it acts as mediator between the investors and the administrators (Brown, 2007). CG has a great deal of interest to the ownership structure of corporations. Shareholders' compensation and board are mostly focused on two things; one is organizational performance and other is CG. Thus, the board members act as mediator between owners and their agents (Leech and Leahy, 1991).

The administrative ownership position relates the management interest with the interest of investors, but it is not as much important because of its uncertain effect on organizational performance (Stulz, 1988). Thomsen and Pedersen (2000) study the relationship between organizational performance and ownership concentration. They find that this relationship depends upon uniqueness of the controlling investors. Owner-controlled organizations are more profitable than administrator-controlled organizations. Ownership provides improved monitoring, which leads to enhanced performance (Agrawal and Knoeber, 1996). The family-controlled organization or family ownership is the ordinary form of business firms on the globe, and it accounts for over 80% of all organizations in the United States (Anderson and Reeb, 2003). Family organizations have better performance compared to nonfamily organizations.

In order to judge the ability of company regarding fulfilling its obligation, cash is the foremost important among items of working capital (WC). Moreover, cash holding is crucial for fulfilling the obligations while the idle cash does not help to increase value of the company. Therefore, it's essential for companies to maintain appropriate cash reserves. The company can enhance their business by optimal level of held reserves, which are also considered as the most important element in analyzing responsibilities of company toward its obligations (Gill and Shah, 2012). CG not only helps in regulating policies, but it also plays active role in controlling WCM, which is abbreviated as WCM (Gill and Biger, 2013).

Similarly, philanthropy is supposed to absolutely impact firm monetary-related efficacy since it supports organizations in sociopolitical welfare, which enables them to rouse consenting results (Dabor *et al.*, 2015). Therefore, the study aims to investigate the impact of basic governance factors on performance of firm via mediating role of board size, philanthropy and WCM. The foremost important and first objective of this study is to identify the impact of ownership structure (OS) and independent directors on board size, WCM and philanthropy of firms (sugar industry) in Pakistan. Second objective of this study is to determine the impact of OS and independent directors on return on equity (ROE), return on asset (ROA) and sales growth of firms. Third objective is to explore the impact of board size, WCM and philanthropy on ROA, ROE and sales growth of firms (sugar industry) in Pakistan.

The study contributes to the existing knowledge in following ways: first, it bridges a gap via providing the evidence of mediating role of board size, philanthropy and WCM between the governance factors and performance. Secondly, it links the WCM with CG to improve the quality of work and better management. Finally, it enhances the need to spend more on philanthropy to highlight the corporate image and hence, better performance. Furthermore, this research will be contribution to corporate sector of Asian countries for analyzing different roles of CG.

1.1 Overview of sugar industry
First major contribution was made for sugar by Arabs in 642 and then followed by crusaders until the first sugar cane plant was recorded in 1,099 in England. In 1,493, Columbus took sugar cane plants to Caribbean, and Portuguese brought sugar cane to Brazil. From 1,625 to 1,750 with American colonization of Europe, Caribbean became largest producer of sugar. Sugar production was mechanized by the end of 18th century.

Modern form of sugar industry established in the subcontinent in early 1930s. At the time of partition, there were seven sugar mills in Pakistani territory. With brisk economic activities and rapid urbanization, demand increased day by day. There were 35 sugar mills by the end of 1980 in Pakistan, and later this figure rose to 45 in 1990. By 2009, total sugar mills were 86 with an annual capacity of 7 million tons. Present sugar consumption has crossed 4 million tons with a value of US$1.8 billion. It is the second largest agro-based industry in Pakistan, which generates Rs. 22 billion revenue to government. It provides direct and indirect jobs to 1.2 million people.

Sugar cane industry is facing many challenges. The price of sugar is based on weight instead of quality, and this fact is hurdle toward quality production. Moreover, government policies on price fixing for sugar cane are another major issue. Further expansion of the industry merely depends on how these issues will be tackled by government. Sugar purity is mainly determined by its sucrose contents. Sugar was bleached by sulphitation process, which is now replaced by carbon process. Production estimate for current year is 5 million tons where the expected consumption will be around 4.337 million tons (based at 24 kg per capita for 180.71 million population).

2. Literature review

OS of the company, size of board and CEO's duality are considered as foremost important components of CG (Arora and Sharma, 2016; Butt and Hasan, 2009). Significant consideration has been given to board size of the companies and their performance in current literature of CG. CG mechanisms like the size of the board and independent director for family and nonfamily ownership have an important influence on organizational performance (Ibrahim, 2011). According to prediction of agency theory, there must be difference of opinion between the owners of corporations (Jensen and Meckling, 1976). If there is widespread ownership and control, there might be conflicts between shareholders and company management. However, in a saturated ownership, the conflicts among major shareholders and minority shareholders got importance. According to the study of (Claessens *et al.*, 2000; Lemmon and Lins, 2003), instead of having direct relationships, divergence of ownership and performance of firm are inversely proportional to each other.

It is evident from various Asian countries that ownership divergence and firm's profitability are in nonlinear relationship with each other (Lin and Lin, 2013; Wiwattanakantang, 2001; Utama *et al.*, 2017). The study of Hanafi *et al.* (2018) also shows significant relationship between ownership and firm performance, especially the saturated ownership increases the performance. Therefore, the policymakers and other stakeholders should pay great attention toward ownership. Outcome showed the reality of a statistically significant nonlinear relationship between ownership and performance. Many organizations analyzed that there is significant and positive relation between foreign holding and organizational performance (Imam and Malik, 2007).

Mudambi and Nicosia (2009) studied the relation between corporate performance and OS. They found that managerial ownership and family ownership of corporate can improve financial performance of company. Lauterbach and Vaninsky (2011) analyzed the data collected from 280 Israeli firms for exploring the relationship between OS and firm's performance. Their study revealed that if managers are owners, then firm's performance will decrease, and in case of family ownership, the firm's performance is worst. Therefore, managerial ownership is more important than family ownership. The study of Itturalde *et al.* (2011) has given new evidence regarding influence of the insider ownership on performance of nonlisted organizations. They distinguished the performance of family and nonfamily organizations by collecting data from 586 Spanish nonlisted organizations, and results of their study highlighted that in family-owned firms, the relationship between insider ownership and organizational performance depends on age group of managers.

Ongore and Owoko (2011) investigated the interrelations among ownership, board and administrator personality by collecting data of firm's performance from 52 organizations listed at the Nairobi Stock Exchange. They measured ROA, ROE and dividend yield and found that the relationships among ownership concentration, government and organizational performance are negative. Zakaria *et al.* (2014) studied the effect of different types of OS on firm's performance. They took four types under consideration including concentrated, foreign, governmental and managerial ownership. The results suggested that managerial or concentrated ownership directly and positively affects firm performance, but government and foreign ownership have less effect on it. There is no specific standard to measure or observe the exact relation between firm performance and OS because for every country and economy, there is sustainable OS. Scholten (2014) examined the data of 80 Dutch companies from 2011 to 2012 and concluded that firms perform better when ownership concentration increases and decrease in ownership concentration will lead to poor firm performance. There is great effect of foreign ownership on inside ownership in decision-making. Foreign ownership has negative and state ownership has positive effect on leverage, whereas managerial ownership also positively affects leverage and OS (Le, 2015). The data of nonfinancial public firms listed in Busra Malaysia taken for five years (2010–2014) highlighted that OS positively affects financial performance (Elvin and Hamid, 2016). Therefore, ownership concentration is directly proportional to firm performance. In order to find the impact of OS on firm performance, (Ahmed and Hadi, 2017) took data of firms located in MENA region (comprising nine countries including Jordan, Bahrain, Oman, Qatar, Tunisia, UAE, Morocco, Kuwait and Egypt). They preferred ROE, ROA and Tobin Q as a standard to measure performance, and results revealed that governmental ownership and insider ownership both positively affect the financial performance of firms in MENA region.

Shahid *et al.* (2018) explored the relationship between elements of CG and performance of cement industry in Pakistan. They found insignificant but positive relationship between size of board and ROE. Moreover, they found that there is significant but negative relationship between financial leverage and ROE. Latif *et al.* (2013) took the data from sugar industry of Pakistan and investigated the relationship between CG mechanism and firm performance. They involved size of board, CEO duality and board composition to check CG mechanism. Whereas ROE was used by them to check the firm performance. The result of their study highlighted that CG and firm performance are in significant relationship.

Like many other researchers, Peng (2004) found the positive relation between size of board and firm performance. Whereas some studies have explained this relationship as negative. Kumar and Singh (2013) investigated the relationship of size of the board with organization worth and found positive relationship between board size and the corporate performance. Malik *et al.* (2014) used Pareto approach in order to investigate the connection between board size and performance of organization, and for this purpose sample of 14 commercial banks was taken from 2008 to 2012. The relationship between bank board size and CG was measured by econometric techniques, and study revealed that there is positive relationship between performance and board size. According to (Jensen, 1993), the financial performance of firm is positively affected by board size. Small board size is more efficient than the big one, and there is strong negative relationship between board size and firm performance (Yermack, 1996). Furthermore, Lehn *et al.* (2004)

found that performance of firms with smaller board size is better than the firms having large board size. According to Hermalin (2005), due to coordination and communication problems, there is possibility that small boards are more effective than large ones. (Lehn *et al.*, 2004; Guest, 2008) explained that the board size is the specific feature of firm and has profound effect on the performance. Similarly, Connelly *et al.* (2012) explained that small boards are more valuable and better for firm performance. Klein (1998); Eisenberg *et al.* (1998); Jell-Ojobor and Windsperger (2014) also found strong negative relationship between board size and profitability of the firm, and large board size leads to miscommunication and poor decision-making. The board size and financial performance of firm have negative relationship (Bennedsen *et al.*, 2010; Adams and Mehran, 2012). Htay (2012) explained that smaller size board is positively associated to financial performance of bank, which is measured by ROE and ROA. In context of Pakistan, the study of Karim and Faiz (2017) investigated positive association between board size and firm performance.

In all types of CG, executive and nonexecutive directors constitute the board comprising nonindependent or independent directors. The nonexecutive directors monitor CEO and other company executive directors' actions to ensure the safety of shareholder's interests. Nonexecutive directors have diverse knowledge and skills as compared to other directors (Weir and Laing, 2001; Abdullah, 2004).

Rhoades *et al.* (2000) measured the impact of outsider or independent directors on financial performance. They found that performance is not dependent on the independency of the directors. Dehaene *et al.* (2001) highlighted the significant relationship among ROE and independent directors, and this relation actually supported the perception that due to monitoring function of independent directors, the interests of shareholders are well guarded (Johl *et al.*, 2015). The existences of independent directors are important because independent directors have access to source of external environment and information, which is inaccessible by dependent directors (Hermalin, 2005). The proportion of the independent director has positive affect on performance of the firm as well as it also increases the bank debt financing and credit rating (Ashbaugh-Skaife *et al.*, 2006).

In recent times toward corporate board, there is a trend with additional independent director to monitor independently and raise the problem of agency faced by the organization. On the board of banks, the existence of independent directors is supposed to increase the compatible compensation reward to managers and earning management (Cornett *et al.*, 2009). Independent directors can independently monitor the management for the best interest of shareholders (i.e. to protect and maximize owner's wealth). The effectiveness of independent directors on firm performance is empirically supported but has diverse findings. Literature revealed that independent directors protect shareholder's interest and mitigate the agency problem (Adams and Mehran, 2012; Hermalin and Weisbach, 1991; Xie *et al.*, 2003). In Pakistan, the study of Khan and Awan (2012) revealed positive association between independent directors and firm's financial performance by measuring ROA and ROE. There is positive relationship among independent directors and firm performance. If this relationship is negative, then it will jeopardize the performance of independent directors (Sharifah *et al.*, 2016). Opposite to these findings, Adams and Mehran (2012) found a negative correlation between abnormal returns and independent directors.

2.1 Relationship among corporate governance, philanthropy, working capital and firms' performance

There are only few studies that have explored the relationship between CG mechanisms and the management efficiency of WC. Uchenna *et al.* (2012) took five top beer manufacturing companies to evaluate the relationship between changes in WC level and its effect on the earning of the firm.

According to Kim *et al.* (1998), the companies having surplus cash are often considered as weak in CG and this cash has no role in generating profit. Gul *et al.* (2013) explored the relationship between WCM and operating profit of the firms listed in Pakistan Stock Exchange. They measured the WC efficiency of the companies through C-R, cash turnover ratio and current-asset-to-sales ratio. Average collection period (ACP), Inventory turnover period (ITOP) and average payment period (APP) and ROA were used as dependent variables. They concluded that there exists a significant relationship between measures of WCM and ROA.

Gill and Mathur (2011) collected the data of Canadian companies in order to explore the relation between board size, board duality and net WC. They found that size of board and duality of board reversely affect net WC. Vahid *et al.* (2012) investigated the impact of WCM (cash holdings) on the performance of firms listed in Tehran Stock Exchange (TSE). They used the data of 83 Iranian companies for the period of 2001–2010. With the application of multiple regression model, they found negative and significant relationship between board size, board duality and net WC. The weakness of CG can lead to inefficient policies of WCM. Moreover, this weakness negatively affects stockholder value. Whereas the influential or strong CG acts as a tool in reserve management system of company (Gill and Biger, 2013). Madishetti and Kibona (2013) determined the impact ACP and APP on the earning before interest and tax (EBIT) or SMEs. They showed that ACP and EBIT are significantly but negatively associated with each other. They found a positive relationship between APP and EBIT.

Jamalinesaria and Soheilib (2015) explained that efficiency of WC is judged by CG mechanisms. "The time taken by a company to pay for the inventory purchased on credit is referred to the average payment period" (Ngwenya, 2012). It is calculated as:

"APP = (Average accounts payable/Cost of purchases) x 365"

Philanthropy is a Greek word that describes social and financial welfare. Traditionally philanthropy is known as general public welfare that focuses on human prosperity (Masulis and Reza, 2014). The idea of philanthropy opens the activities for welfare of general public by concentrating on their prosperity. It comprises several dimensions, for example, monetary gifts, improvement of framework, regular affliction and support in administrative activities (Seifert *et al.*, 2004). According to Saiia *et al.* (2003), philanthropy is proclivity by the organizations working for human welfare.

Executives of companies must possess the ability to show the company's profitability to patrons, which is result of charitable works. Many studies have discussed that firm-specific variables have great influence on firm's performance, and these variables include age, firm size and leverage. Dabor *et al.* (2015) examined that there is significant effect of philanthropy on financial efficacy of firm because organizations are interested in sociopolitical welfare, which leads to favorable results. Mahmood *et al.* (2018) used the data of firms listed in Pakistan Stock Exchange for the period of 15 years (i.e from 2004 to 2018) and investigated the moderating effect of strategic philanthropy between relation of CG and firm's performance. Their study revealed that with moderating role of philanthropy, CG significantly affects firm performance.

3. Data and methodology

In this study, independent directors and OS are taken as independent variables while ROA/investment, ROE and sales growth are used as proxy variables for firms' performance. However, size of the board, philanthropy and WCM (APP = average payment period) mediate the relationship between independent and dependent variables. The data is collected from Balance sheet analysis issued by State Bank of Pakistan and annual reports of 32 food companies and sugar mills listed at Pakistan Stock Exchange of Pakistan for the period of four years, 2014–2017. Generalized least squares statistical method is used to measure the relationship. The study has the following theoretical framework and hypotheses.

H1. There is no relationship between board size and ROA.

H2. There is no relationship between board size and ROE.

H3. There is no relationship between board size and sales growth.

$$\mathrm{PhT}_{it} = \beta_{1i} + \beta_2\,\mathrm{OWN}_{it} + \beta_3\,\mathrm{ID}_{it} + \mu_{it}$$

where ROA = Return on Assets, ROE = Return on Equity, Board Size = Board Size, OWN = Ownership structure, ID = Independent Directors, PhT = Philanthropy, WCM = Working Capital Management.

4. Results

Table 1 shows that there is significant (p-value = 0.0443) and positive (7.63324) relationship between independent directors and ROA (firms' performance) showing as the independent directors increase in board of firms, the ROA also increases, thus rejecting H7. It is also found that both board size and OS have negative but insignificant relationship with ROA, thus H1 and H4 can be partially rejected. It is clear from the table that there exists significant and positive relationship between philanthropy and ROA; therefore, H19 is rejected. On the other hand, WCM has significant and negative relationship with ROA, which means as the APP decreases, the ROA of sugar firms increases; thus, Ho16 is also rejected.

Table 2 shows that there is significant (p-value = 0.0013) and negative (−30.647) relationship exists between OS and ROE, which means as more firms are family-owned, the ROE decreases in food industry of Pakistan, thus rejecting H5. On the other hand, H2 and H8 can be partially rejected as both board size and independent directors have positive but insignificant relationship with ROE. It is clear from the table that there exists significant and positive relationship between philanthropy and ROE, which means as the amount of donations increases, ROE also increases; therefore, H20 is rejected. On the other hand, WCM has significant and negative relationship with ROE, which means as the APP decreases, the ROE of sugar firms increases; thus, H17 is also rejected.

Table 3 shows that there is significant (p-value = 0.041) and negative (−10.7912) relationship between board size and sales growth, which means as the board size increases,

Variable	Coefficient	t-Statistic	p-values
C	11.8287	0.847	0.3986
Board size	−1.7053	−0.8867	0.377
Ownership structure	−6.0766	−1.6555	0.1004
Independent directors	7.63324	2.03223	0.0443
Philanthropy	0.736536	2.604548	0.0098
WCM (APP)	−0.03830	−3.827876	0.0002

Table 1. The impact of board size, independent directors, ownership structure, philanthropy and WCM on ROA (return on assets)

Variable	Coefficient	t-Statistic	p-values

Results of SEM

5. Conclusion

The results are concluded in the framework of sugar mills. The study finds significant and positive relationship between independent directors and ROA (firms' performance) showing that the increase in independent directors in board of firm will also increase the ROA. Similarly, there exists a significant and negative relationship between OS and ROE, which means that as more firms are family-owned, the ROE will decrease. There is significant and negative relationship between board size and sales growth as the increase in board size will decrease the sales growth, thus rejecting H3, H5 and H7. The OS has positive and insignificant relationship with the board size; thus, board size does not mediate the relationship between OS and outcome variables (ROA, ROE and sales growth). Independent directors have a significant relationship with the board size; thus, board size mediates the relationship between OS and sales growth. However, it does not mediate the relationship between independent directors and other dependent variables (ROA and ROE) because board size has insignificant relationship with ROA and ROE. On the other hand, it is clear from the results that philanthropy has significant and positive relationship with ROA, ROE and sales growth; therefore, H19, H20 and H21 are rejected. WCM has significant and negative relationship with ROA, ROE and sales growth; thus, H16, H17 and H18 are also rejected. It is also clear that both OS and independent directors have significant relationship with philanthropy and WCM; thus, philanthropy and WCM mediate the relationship between independent variables (OS and independent directors) and dependent variables (ROA, ROE and sales growth). The rest of constructed hypotheses can be partially rejected. CG maintains a basic role in the performance of the organization. The results suggest that the board of directors should make sure that the decisions are made for benefit of all stakeholders and the role of independent director should be increased in the sugar sector firms of Pakistan. Finally, the ownership is very important in the organizations. Organizations should increase the nonfamily ownership in firms for better corporate performance.

6. Limitations and future recommendations

This study has several limitations among which first limitation is that this research only focused on sugar industry and in future the researchers can conduct similar research on any other manufacturing industry. Secondly, this research is limited to CG of Pakistani companies. Therefore, this study can be replicated in context of any other Asian country. Moreover, this study can be extended by adding variable of responsible leadership or green financing.

Notes

1. Institute of Chartered Accountant of Pakistan (ICAP) is responsible to regulate the profession of accounting in Pakistan and was established on July 1, 1961 https://www.icap.org.pk/about-icap/.
2. "Securities and Exchange Commission of Pakistan is governmental entity that has the legal authority to enforce financial reporting requirements and exert other controls over entities that participate in the capital markets within their jurisdiction".
3. International Financial Reporting Standards: Framework for the Preparation and Presentation of Financial Statements, which sets forth the concepts that underlie the preparation and presentation of financial statements for external uses.

Abstract: Investors can use Corporate Risk Disclosure to guide them in assessing a company. Indicators of Corporate Risk Disclosure, based on IFRS 7, include 45 items with the following requirements: (a) General Risk Information; (b) Accounting Policies; (c) Financial Instrument; (d) Derivative hedging; (e) Reserve; and (f) Financial and Other Risks. The current study aims to assess and analyze the impact of Corporate Risk Disclosure on Cost of Equity Capital and to determine whether Firm Performance moderates the relationship between Corporate Risk Disclosure and Cost of Equity Capital. It uses a sample of 86 manufacturing companies listed in Indonesia Stock Exchange in the period 2017-2019. The results indicated that Corporate Risk Disclosure negatively affects Cost of Equity Capital. More risk items disclosed means higher market liquidity as demand for securities is increasing and thereby lowering the cost of equity capital. Firm performance has been shown to strengthen the impact of Corporate Risk Disclosure on Cost of Equity. Underperforming companies tend to disclose more risk information than their well-performing counterparts and the latter, thereby, will have lower cost of equity capital.

Keywords: Corporate Risk Disclosure, Firm performance, Cost of Equity Capital

1. Introduction

Corporate risk disclosure has gained special attention in the global stakeholder communities (Aebi et al., 2012; Beltratti dan Stulz, 2012; Erkens et al., 2012). Studies by Botosan (1997), Lajili (2009) and Linsley and Shrives (2006) elucidated the costs and benefits of disclosure and maintain that higher level of disclosure leads to more transparency, lower cost of capital, and decreased information asymmetry. An example of this is the mining case of PT. Newmont that produced a large amount of mine tailings, caused pollution, and disturbed the ecological balance of West Nusa Tenggara, Indonesia in 2016. Another example that represents the case of negative externalities as the impact of industrialization is the destruction of natural ecosystem caused by PT. Riau Andalan Pulp and Paper in 2015. High production capacity of PT. Riau Andalan Pulp and Paper requires it to cut down trees in a large scale, which makes the forest condition even worse. Companies lacking real care for environmental issues in their operation will end up causing environmental damages and degrading their business performance.
From a business perspective, disclosing company risk can reduce the cost of capital, because investors believe that business operations run well when uncertainty diminishes (Abraham

and Cox, 2007; Linsley and Shrives, 2006). Disclosure of financial information is mandatory for companies seeking to go public. Positive company information regarding expected returns will influence shareholders and potential investors. Unexpected negative information, on the contrary, will have a negative impact on the market. In a contractual relationship, management has a choice to use a combination of debt and equity financing.

Considering the importance of risk disclosure, standard-setters seek to further reform the existing regulations in recent years, including the issuance of IFRS 7 to regulate and guide accounting disclosure practices—depending on the mandate extended. IFRS 7 comes with the objective that entities shall provide information regarding company's financial position, performance, cash flow, and risks associated with financial instruments and management policies. IFRS 7 includes disclosure about financial instruments applicable to all enterprises as it combines the requirements for disclosure of financial instruments, which formerly regulated under International Accounting Standards (IAS). IFRS 7 requires qualitative and quantitative disclosures for three main risks: credit risk, liquidity risk and market risk.

Qualitative disclosure is intended to describe how the company is exposed to the risks, how the risks arise and how it manages these risks. Quantitative disclosure, on the other hand, is designed to provide information concerning the extent to which an entity discloses the risks based on information provided internally for the management. Capital market regulations serve as regulatory tools to effectively provide the required information. Disclosure may benefit firms through lower cost of capital for the following reasons: (1) Disclosure reduces transaction cost figure. Increase in disclosure helps investors reduce adverse selection component of their bid-ask spreads and cost of equity capital (Botosan, 1997). Disclosure reduces the adverse price impact associated with large-scale trade; reduces information asymmetry between investors, which leads to a higher demand for securities in the market; and reduces cost of transaction and increases liquidity, which in turn reduces cost of equity capital (Amihud and Mendelson, 1986; Botosan, 1997; Verrecchia, 1991). Increased disclosure also lowers uncertainty or estimation risk (Clarkson et al., 1996). Botosan (1997) suggests that firm enhancing disclosure is an attempt to reduce the cost of equity capital by lowering non-diversifiable estimation risk.

Prior research has examined the relationship between disclosure level (financial and social) and cost of equity capital, and the results have been varied because of the disclosure validity and certain measures used to measure the cost of equity capital (Al-Tuwaijri et al. , 2004). Negative relation exists between financial disclosure and cost of equity capital (Botosan, 2004; Healy and Palepu, 1999; Richardson and Welker, 2001). However, there is a significant positive relation between social disclosures and the cost of equity capital because some biases in social disclosure might benefit companies through its impact on organizational stakeholders rather than on other investors (Richardson and Welker, 2001). Lambert et al. (2007) examined the direct and indirect effects of disclosure quality on the cost of capital. Higher quality disclosures affect the firm's assessed covariances with other firms' cash flows and also indirectly affect the company's investment decisions in the future. The results of study showed that disclosures have a direct negative impact and an indirect positive impact on cost of capital.

Information disclosure is an attempt to bring a harmony of interests between stakeholders and managers by lowering agency cost and, thus, improve company's performance (Solomon et al., 2000). Healy and Palepu (1999) maintained that disclosure communicates corporate governance and firm performance to stakeholders. Previous studies provide evidence that voluntary disclosure provides an important mechanism that improves firm performance (Healy and Palepu, 1999; Miller and Noulas, 1996). Agency theory suggests that the relationship between business principals and their agents requires efficient use of information to minimize information asymmetry (Eisenhardt, 1989). Agency theory explores two potential problems (adverse selection and moral hazard) that may arise in the manager-shareholder relationship for low corporate disclosure. Foerster et al. (2014) found that corporate management disclosures in Canada have been positively related to firm value in two aspects: reducing business risk and changes in investors' perceptions of future cash flows. Callahan and Smith (2004) found that financial disclosure is positively related to future performance of corporate industries.

Results of study related to corporate risk disclosure and those that moderate risk disclosure, cost of capital and performance remain limited (Aebi et al., 2012). The current study analyzes the relationship among three variables—risk disclosure, cost of capital and performance—in developing country settings where disclosing risk information is a matter of options rather than obligations. Based on the above mentioned phenomenon, we formulate the research problem as follows:

a) Does corporate risk disclosure affect cost of equity capital?
b) Does firm performance strengthen the impact of corporate risk disclosure on the cost of equity capital?

2. Literature Review

Literature Review

Corporate Risk Disclosure

Cabedo and Tirado (2004, 184) define risks as a series of internal and external factors that condition a corporation's wealth, challenges, opportunities and threats. By the term risk they mean the possible loss or potential enhancement in corporations' wealth that arise from the interaction of these factors. Linsley and Shrives (2006) add that risk is a characteristic of every opportunity, prospect, danger, threat, which impacts the company in the future. While there are relevant concerns over potential losses, it is clear that risk must consist of two-sided volatility concerns about both potential gains and losses. Corporate risk disclosure is defined as the reporting of conditions that may cause the company's value to increase or decrease as well as the steps to be taken to minimize these risks (Hassan, 2009).

Firm Performance

Performance is the output or accomplishment of company's operational activities in utilizing the available resources. The company's strategy from a financial perspective will affect shareholder value in the long run. Return on Assets (ROA) serves to indicate how profitable a company is relative to its assets or the resources it owns. According to Lestari and Sugiharto (2007) ROA is a financial ratio that indicates the net profit that a company earns in relation to its assets. To put it another way, the higher the ratio the better the asset productivity is in obtaining net profits. The higher the ROA figures, the better the firm performance is, because its rate of return on investment of will be higher.

Cost of Equity Capital

Cost of equity capital (COC) is the cost to pay for the spending resources (source of financing). Cost of equity capital can be identified as the minimum return required to pay for the equity capital invested (Modigliani and Miller, 1958). Cost of equity correlates with the risk of investing in company shares. Things assumed in estimating the cost of capital are business and financial risks that remain constant (or relatively stable). Companies can raise equity capital in two ways: (1) retained earnings, and (2) issuing new shares. This is done to raise new funds required for the company's operation (Brigham and Houston, 2006: 105).

Companies have an obligation to disclose financial information which certainly has an impact on the incurred costs. Therefore, the cost of equity capital referred to in this study is the cost incurred by the company for providing information to the public; shareholders, investors, government, creditors, and the general public (Tarjo, 2008).
The cost of capital is calculated on the basis of the long-term sources of funds available to the company. There are four long-term sources of funds: (1) long-term debt, (2) preferred stock, (3) common stock, and (4) retained earnings. Long-term cost of debt is the current after-tax cost of debt to borrow long-term funds through loans. The cost of preferred stock is the annual dividend of preferred stock divided by the proceeds from selling the preferred stock. The cost of common stock capital is the rate used by investors to discount dividends that are expected to be paid out in the future. The measurement of cost of common stock capital (cost of equity capital) is affected by the company valuation model used. The following are valuation models for cost of equity capital (Utami, 2005):

1) Constant Growth Valuation Model or Gordon Growth Model. The rationale for this model is that the stock value equals the cash value (present value) of all dividends to be received in the future at a constant growth rate indefinitely.
2) Capital Asset Pricing Model (CAPM). Based on this model, the cost of ordinary share capital is the rate of return expected by investors as compensation for undiversifiable risk as measured by beta coefficient.
3) Ohlson Model. The model is used to estimate firm value based on book values and cash value of abnormal earnings.

The present study used Cost of Equity Capital measured using Capital Asset Pricing Model (CAPM). The latter is the rate of return expected by investors as compensation for undiversifiable risk as measured by beta coefficient. In this study, we employed CAPM to measure cost of equity capital because it generates accurate and correct estimation.

Research Model

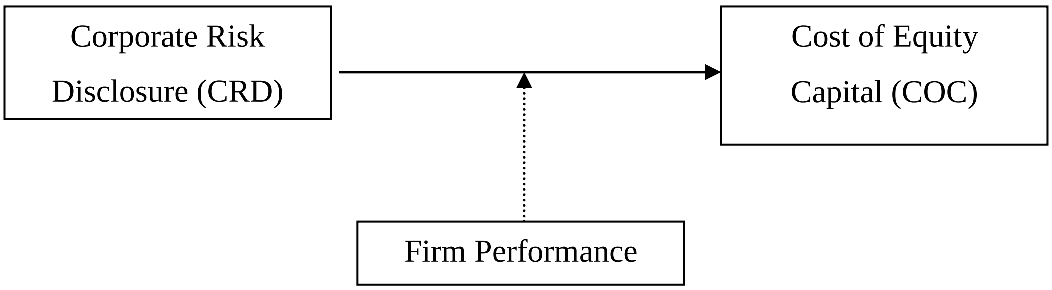

Figure 1 : Research Framework

3. Method

Population and Sample

The population in this study consisted of all manufacturing companies listed on Indonesia Stock Exchange for the period 2017-2019. We use purposive sampling techniques to collect samples that meet the following criteria: (1) companies publishing annual report; (2) companies using rupiah; (3) companies reporting their earnings during study; and (4) companies not getting delisted. The study uses a sample of 86 companies per year. The table below details the sampling criteria:

Tabel 1. Population and sample

Sampling Criteria	Number
Total number of manufacturing companies.	145
Companies not publishing annual report	(15)
Companies using currency other than Rupiah.	(17)
Companies reporting net loss.	(18)
Companies not getting delisted.	(9)
Total	**86**

Sources: Indonesia Stock Exchange

Variables and Measurments

1) Corporate Risk Disclosure

As adopted in Hassan (2009), Corporate Risk Disclosure is the number of financial risks that firms present in their annual reports that consist of 45 items. Risk disclosure can be divided into: (a) General Risk Information; (b) Accounting Policies; (c) Financial Instrument; (d) Derivative hedging; (e) Reserve; and (f) Financial and other risks. The extent of financial risk disclosure in this study is indicated by scores: 1 is assigned when the items are presented in the annual report; and 0 is assigned when the items are not presented in the annual report. Financial risk disclosure can be measured by summing up the total score of disclosure for each annual report. The equation used to quantitatively measure the extent of financial risk disclosure in this study is presented below:

$$CRD = \frac{1}{MAX} \sum SCORE$$

Where, CRD = Disclosure score
MAX = Maximum value a company can achieve
SCORE = Score for each item of corporate risk disclosure
(1 and 0 for available and not available, respectively).

2) Firm Performance

To identify firm performance, we use Return on Assets (ROA) as indicated by the following formula:

$$ROA = \text{Net Incone} / \text{Total Asset}$$

3) Cost of Equity Capital

By cost of equity capital we mean the cost that the firm has to bear for providing information to the public and, thus, anticipating the risks by increasing the required rate of return on shares. Furthermore, Cost of Capital (COC) in this study is calculated by Capital Asset Pricing Model (CAPM). The method calculating COC using CAPM has been adopted by Mardiyah (2002) and Heriyanthi (2013). COC approximation using Capital Asset Pricing Model (CAPM) is represented in the following formula:

$$COC = Rft + \beta i\ (RMt - Rft)$$

Where,
Rft : Free-risk return as proxied by the 1-month Bank Indonesia's interest rate.

RMt : Market return of the Composite Stock Price Index (CSPI) on day t plus CSPI on day t-1 divided by CSPI on day t-1.
βi : Unsystematic risk for each company share i

4) Control Variable : Leverage dan Size
The control variables used in this study includes:
(a) LEV (Leverage) as measured using debt-to-asset ratio. Debt-to-asset ratio has been widely used as leverage proxies in previous studies (Amran et al., 2009; Oliviera et al., 2011). Debt-to-asset ratio is, by definition, the total amount of a company's liabilities divided by the total amount of the company's assets.
(b) SIZE, is the firm size as measured by Ln Total Asset over the period of the study.

4. Result and Discussion

Corporate Risk Disclosure affects Cost of Equity Capital

Based on the multiple linear regression analysis of Model 1 regression equation, the formula is written as follows:

$$COC = 0.560 - 0.306\ CDR + 0.038\ LEV + 0.008\ SIZE + e$$

Table 2. Determination Test

R	R Square	Adj R Square	Std Error of the Estimate
0.409	0.167	0.157	0.24667

Sources: processed

Table 3. ANOVA and T-test

ANOVA		
F		**Sig.**
17.010		0.000
Uji t		
Unstandardized Coefficients		**Sig.**
Constant	0.560	
CRD	-0.306	0.000
LEV	0.038	0.777
SIZE	0.008	0.860

Sources: processed

The adjusted r-squared value, as we can see in Table 1, is 0.157, which means that 15.7% variation in cost of equity capital can be explained by Corporate Risk Disclosure, while the remaining 84.3% can be explained by other variables not included in the model. The results of ANOVA indicate Sig. 000 at $\alpha = 5\%$, which means that the regression model is adequate to estimate the effect of Corporate Risk Disclosure on Cost of Equity Capital. Regression testing for Model 1 in Table 2 indicates the t-test value of 0.306 with Sig. 0.000 at $\alpha = 5\%$. This confirms that the result of this study is consistent with those of Botosan (1997) and Dhaliwal et al (2001). As suggested above, Corporate Risk Disclosure has a negative effect on Cost of Equity Capital. The more extensive the financial risks disclosure is, the lower the cost of equity capital will be. The more items disclosed, the higher the market liquidity is; for the reason that increased demand for securities will decrease the cost of equity capital.
Extensive disclosure lowers unanticipated risks and therefore reduces compensation costs for investors. According to Hassan (2009), risk disclosure that requires (a) General Risk Information (b) Accounting Policies (c) Financial Instrument (d) Derivative hedging (e) Reserve (f) Financial and Other Risks provides crucial information for investors to asses firm capability to survive and to meet its short-term and long-term obligations as well as to

estimate return on their investments. The regression analysis for Leverage as the control variable indicates no effect on cost of equity capital with Sig. 0.777 which is greater than α = 5%. Companies with funding structure that adopts Leverage technique need to maintain their liquidity to enable them to pay short-term and long-term debts. The regression analysis for Size as the control variable indicates Sig. 0.860, which is greater than α = 5%. This indicates that firm size has no effect on cost of equity capital. Both large and small companies incur costs to provide information to stakeholders.

Corporate Risk Disclosure and Firm Performance affect Cost Of Equity Capital

Based on the multiple linear regression analysis of Model 2 regression equation, the formula is written as follows

$$COC = 0.471 – 0.278\ CDR + 0.132\ FP - 0.171\ CDR*FP + 0.102\ LEV – 0.02\ SIZE + e$$

Model 2 adds up Firm Performance to determine the effect of Corporate Risk Disclosure on Cost of Equity Capital.

Table 4. Determination Test

R	R Square	Adj R Square	Std Error of the Estimate
0.488	0.238	0.223	0.23683

Sources: processed

Table 5. ANOVA and T-Test

ANOVA		
F		**Sig.**
15.780		0.000
t-test		
Unstandardized Coefficients		**Sig.**
Constant	0.471	
CRD	-0.278	0.014
FP	0.132	0.000
LEV	0.102	0.434
SIZE	-0.02	0.969
MODERATE	-0.171	0.000

Sources: processed

The adjusted r-squared value, as can seen in Table 3, is 0.223, which means that 22.3% variation in Cost of Equity Capital can be explained by Corporate Risk Disclosure and Firm Performance, while the remaining 77.7% can be explained by other variables not included in the model. The results of ANOVA indicate Sig. 0.000 at α = 5%, which means that the regression model is adequate to estimate the effect of Corporate Risk Disclosure and Firm Performance on Cost of Equity Capital. Regression testing for Model 2 in Table 4 indicates that Corporate Risk Disclosure affects Cost of Equity Capital with Sig. 0.014 at α = 5%. In addition, Firm Performance affects Cost of Equity Capital with Sig. 0.000 at α = 5%. Leverage and Size have no effect on Cost of Equity Capital. This confirms that the Model 2 regression analysis is consistent with Nahar and Azim (2017) stating that Firm Performance as the moderating variable is indicated with Sig. MODERATE of 0.000 at α = 5%. Firm Performance strengthen the effect of Corporate Risk Disclosure on Cost of Equity Capital as indicated by negative coefficient of -0.171 and increased Adjusted R-Squared Value of 0.157 (Table 1) to 0.223 (Table 2).

Corporate Risk Disclosure items are more commonly presented by poor-performing firms, because more extensive risk disclosure may avoid surprising information that leads to a negative market reaction. Investors' assessment of the company profile can be indicated by the level of transparency. Sophisticated and knowledgeable investors can assess firm performance more accurately (Deumes and Knechel, 2008) and risk disclosure helps companies improve their performance. Corporate Risk Disclosure is not mandatory for companies in developing countries. Based on agency theory, management needs shareholders' supervision to ensure that the business process runs effectively and efficiently (Jensen and Meckling, 1976). Contractual relationships require transparency with regard to positive and negative information about the expected returns. Corporate management can determine the best combination of financial structures through debt or equity. Debt and equity are important components in decision making concerning the financial structure of a business (Dhaliwa et al., 2011). Shareholders will react positively if the return on investment is greater than the cost of capital, which in turn improves the company's performance. The cost of capital is an important factor in determining the best company's financial structure (Dhaliwal et al., 2011).

5. Conclusions

The above analysis and discussion have led us to the conclusion that:

Corporrate Risk Disclosure affects Cost of Equity Capital

Higher levels of Corporate Risk Disclosure can lead to lower Cost of Equity Capital. Extensive disclosure reduces unpredictable risks and therefore lowers the cost of compensation for investors. Risk disclosure practices require disclosing of: (a) General Risk Information; (b) Accounting Policies; (c) Financial Instrument; (d) Derivative hedging; (e) Reserve; and (f) Financial and Other Risk. This provides investors with crucial information to assess firms' capability to survive and to meet their short-term and long-term obligations, as well as to estimate their return on investments.

Firm Performance strengthens the impact of Corporate Risk Disclosure on Cost of Equity Capital.

Corporate Risk Disclosure items are more commonly presented by poor-performing firms, because more extensive risk disclosure may avoid surprising information that leads to negative market reactions. Investors' assessment of the company profile can be indicated by the level of transparency. Corporate Risk Disclosure is not mandatory for companies in developing countries.

Acknowledgements

This study was supported by STIESIA Surabaya and Darma Cendikia Catholic University.

We would like to thank Prof. Dr. Budiyanto, MS for his presentation of statistical materials; Dr. Suhermin, MM for her research theory and methods; Dr. Lilis Ardini, M.Si, Ak, CA and Dr. Triyonowati, MS for the reviews on paper writing and research method; and Dr. Y. Budi Hermanto, MM, the Chancellor of Darma Cendika Catholic University, for his constructive commentaries.

We wish to thank our colleagues from Doctoral Programs in Management Science of STIESIA Surabaya, Class of 21st, for their helpful contribution to this study.

Last but not least, we would also like to thank Dr. Thyophoida WSP, MM, the Dean of the Faculty of Economics, for his support and encouragement.

Investigating the Interaction of Earning Quality and Information Asymmetry in the Banking Industry Using Simultaneous Equation System

Leila Vasegh Abadshapoori[*]
Amin Nazemi[**]
Navid Reza Namazi[***]

Abstract

Objective: Accounting information in financial markets is as a basis for deciding on the optimal allocation of limited financial resources. Also it is performance appraisal and the perspective of cash flows of investments or loans granted by the organization. Economic decisions of depositors and borrowers in the banking industry are made based on the quantity and quality of their information. The information of these banks, including earnings, must have the necessary quality characteristics in order to distribute financial resources among the members of the society in the best way along the decisions of information users. This can lead to an improvement in the economy and the growth of the banking system. Therefore, the purpose of this study is to investigate the interaction between earning quality and information asymmetry in the banking industry.

Method: To achieve the purpose of the research, data of 11 banks listed on the Tehran Stock Exchange (TSE) and Iran of OTC during a period of 11 years for the years 2007-2018 using the Rah Avard Novin, financial statements and the official site of the Tehran Stock Exchange was collected and analyzed using the structural equation method (SEM) and the two-way Granger causality test.

Results: The findings showed that information asymmetry in the banking industry is high and their earning quality is low. Information asymmetry has a negative effect on earning quality. On the other hand, if the quality of earning is low, it will increase information asymmetry. As a result, earnings quality also has a negative effect on information asymmetry. Finally, bilaterally, these two variables are the cause and effect of each other and have interaction.
The most important risk of the banking industry is their credit risk, which is due to the increase in debt to banks' capital. Another point is that most of the assets of banks are receivables from the provision of facilities, but depending on the steps through which the repayment of receivables, policies and regulatory tools can be repaid can lead to instability of banks.

Abstract

Conclusion: In the banking industry, the information gap is high, so the manager can present the amount of declared earning in the financial statements differently from the actual earning. In this case, the quality of earning decreases and leads depositors and borrowers to incorrect financial decisions. Wrong economic decisions lead to incorrect distribution of financial resources among members of society. In order not to reflect the instability of banks, managers may manage their profits, which implies low profit quality, and as a result, other people active in the capital market will be deprived of complete and transparent information within the organization. These conditions increase the information asymmetry surrounding the banking industry.

بررسی تأثیر متقابل کیفیت سود و عدم تقارن اطلاعاتی در صنعت بانکداری با استفاده از سیستم معادلات هم‌زمان

لیلا واثق‌آباد شاپوری*

امین ناظمی**

نویدرضا نمازی***

چکیده

هدف: تصمیمات اقتصادی سپرده‌گذاران و گیرندگان تسهیلات در صنعت بانکداری، بر مبنای کمیت و کیفیت اطلاعات آن‌ها اتخاذ می‌شود. اطلاعات این بانک‌ها از جمله سود باید ویژگی‌های کیفی لازم را داشته باشد تا در امتداد تصمیمات استفاده‌کنندگان اطلاعات، توزیع منابع مالی بین افراد جامعه به بهترین شکل صورت گیرد تا منجر به بهبود اقتصاد و رشد نظام بانکداری شود. بنابراین، هدف این پژوهش بررسی تأثیر متقابل کیفیت سود و عدم تقارن اطلاعاتی در صنعت بانکداری است.

روش: در راستای هدف پژوهش، داده‌های ۱۱ بانک پذیرفته شده در بورس اوراق بهادار تهران و فرابورس ایران طی بازه زمانی ۱۱ ساله برای سال‌های ۱۳۹۷-۱۳۸۷ با استفاده از نرم‌افزار ره‌آورد نوین، صورت‌های مالی و سایت رسمی بورس اوراق بهادار تهران جمع‌آوری و به کمک روش معادلات ساختاری و آزمون علیت دوطرفه گرنجری، تحلیل شد.

یافته‌ها: یافته‌ها نشان داد که عدم تقارن اطلاعاتی در صنعت بانکداری سطح بالایی دارد و سطح کیفیت سود آن‌ها پایین است. عدم تقارن اطلاعاتی بر کیفیت سود تأثیر منفی دارد. از طرفی اگر کیفیت سود پایین باشد باعث افزایش عدم تقارن اطلاعاتی می‌شود. در نتیجه کیفیت سود بر عدم تقارن اطلاعاتی نیز تأثیر منفی دارد. در نهایت به شکل دوطرفه این دو متغیر علت و معلول یکدیگرند و تأثیر متقابل هم دارند.

نتیجه‌گیری: در صنعت بانکداری شکاف اطلاعاتی بالا است، در نتیجه مدیر می‌تواند مبلغ سود اظهاری در صورت‌های مالی را متفاوت از سود واقعی ارائه دهد. در این صورت کیفیت سود پایین آمده و منجر به تصمیمات مالی ناصحیح سپرده‌گذاران و گیرندگان تسهیلات می‌شود. تصمیمات نادرست اقتصادی موجب توزیع نادرست منابع مالی بین افراد جامعه می‌گردد.

مقدمه

اطلاعات حسابداری در بازارهای مالی به عنوان مبنایی برای تصمیم‌گیری درمورد تخصیص بهینه منابع محدود مالی و ارزیابی عملکرد، دور نمای جریان‌های نقدی سرمایه‌گذاری‌ها یا وام‌های اعطایی سازمان است (فرانسیس و همکاران[1]، ۲۰۰۴). در نتیجه، آثار و پیامدهای کیفیت اطلاعات حسابداری، مورد توجه سرمایه‌گذاران، مدیران، قانون‌گذاران و تدوین‌کنندگان استانداردها است (باتاچاریا و همکاران[2]، ۲۰۱۲). فلاوردی و وون سلمز[3] (۲۰۰۷) اطلاعات را داده‌های خام پردازش شده تعریف می‌کند که با تفسیر این اطلاعات آگاهی به وجود می‌آید و بر مبنای همین آگاهی، تصمیمات اتخاذ و نتایج اقتصادی آن مشخص می‌شود. بخشی از اطلاعات حسابداری در قالب مفهوم سود به ذینفعان صورت‌های مالی گزارش می‌شود. طبق تعریف باربریس و هوانگ[4] (۲۰۰۱)، کیفت سود حدی از صداقت تعریف شده است که عایدات گزارش شده را نشان می‌دهد. در شرایطی که اطلاعات از جمله سود به شکلی شفاف تهیه و به ذینفعان ارائه نشود، بین رقم واقعی سود و مبلغی که در صورت‌های مالی گزارش می‌شود شکافی ایجاد شده و از آن‌جایی که امکان دارد سود توسط مدیر دستکاری شود، می‌تواند با سود واقعی متفاوت باشد. بنابراین، سود ابرازی همیشه نمی‌تواند معیار خوبی برای تصمیم‌گیری باشد. از این رو، علاوه بر کمیت سود باید به کیفیت آن نیز توجه کرد (نمازی و رضایی، ۱۳۹۱).

یک سفارش خرید یا فروش خاص ناشی از وجود یک سرمایه‌گذار با اطلاعات خصوصی، تعریفی از حدود عدم تقارن اطلاعاتی است (باتاچاریا و همکاران، ۲۰۱۲). در بازارهای سرمایه‌ای که توزیع اطلاعات نامتقارن است، فروشنده به دلیل داشتن برتری اطلاعاتی نسبت به خریدار، قیمت بالاتری را برای سهام پیشنهاد می‌دهد که این فاصله قیمت پیشنهادی خریدار و فروشنده نمایانگر سطح عدم تقارن اطلاعاتی است (فرانسیس و همکاران، ۲۰۰۴). بنابراین، جهت اتخاذ تصمیم صحیح به‌وسیله سرمایه‌گذاران، اطلاعات حسابداری باید تضاد منافع و عدم تقارن اطلاعاتی را کاهش دهد. در این صورت کارایی بازار افزایش می‌یابد و اطمینان تصمیم‌گیران اقتصادی نیز محقق می‌گردد. حال این پرسش مطرح می‌شود که اگر فاصله بین سود واقعی و سود گزارش شده کمتر باشد و کیفیت سود بالا باشد، شکاف اطلاعاتی بین مدیر و مالک یا عدم تقارن اطلاعاتی نیز کاهش می‌یابد؟

کیفیت بالای اطلاعات افشا شده، عدم تقارن اطلاعاتی را در بازار سرمایه کاهش می‌دهد. میزان و نحوه جمع‌آوری و افشای اطلاعات توسط مدیریت در عدم تقارن اطلاعاتی بین مالک و مدیر نقش دارد، به این صورت که مدیر به دلیل وجود فرصت‌های رشد و سرمایه‌گذاری امکان دستکاری بیشتر صورت‌های مالی را دارد و در جهت انتقال منابع و مزایا به خود در تلاش است. این فعالیت‌های مدیریت از ارزش شرکت کاسته و هزینه‌های نمایندگی را در بر دارد (قربانی و همکاران، ۱۳۹۲). از دیگر پرسش‌های پژوهش که مطرح می‌شود این است که آیا عدم تقارن اطلاعاتی بر کیفیت سود گزارش شده توسط مدیریت تأثیر دارد؟ با توجه به دو پرسش مهمی مطرح شده، به نظر می‌رسد رابطه دو طرفه بین

کیفیت سود و عدم تقارن اطلاعاتی وجود داشته باشد. بنابراین، پژوهش حاضر به دنبال بررسی این رابطه به صورت متقابل و هم‌زمان است.

بانک‌ها به عنوان یک واسط وجوه مالی میان سپرده‌گذاران و متقاضیان دریافت تسهیلات، با پدیده عدم تقارن اطلاعاتی روبرو هستند، زیرا اغلب آن‌ها شناخت کافی و اصولی از متقاضیان تسهیلات خود ندارند. بنابراین، بانک‌ها در انجام فعالیت خود که ارائه تسهیلات از محل سپرده های عمومی است، دچار مشکل می شوند، به این معنی که اعتبارات به شکل ناکارا تخصیص و در نتیجه ریسک اعتباری بانک افزایش می یابد (مکیان و محبی، ۱۳۹۲، ۷۶). شبکه بانکی با جمع آوری منابع پراکنده و قرار دادن آن در اختیار سرمایه گذاران، باعث رشد سرمایه گذاری و در نهایت رشد درآمد ملی و بهبود رفاه جامعه می شود. در کشورهای درحال توسعه از جمله ایران میزان درآمد سرانه پایین و میل به مصرف بالا است. در نتیجه میزان پس انداز و منابع مالی برای سرمایه‌گذاری‌ها اندک و پراکنده است. لذا، بانک‌ها و مؤسسات پولی نقش مهم‌تری را برای تجهیز منابع و تخصیص مطلوب آن ایفا می کنند (مجتهد و حسن‌زاده، ۲۰۰۳).

مسئله‌ای که وجود دارد این است که در صنعت بانکداری تأثیر کیفیت سود و عدم تقارن اطلاعاتی با وجود رابطه علی بین آن‌ها، مورد بررسی قرار نگرفته است و در نتیجه چگونگی تأثیر متقابل آن‌ها و هم‌زمانی آن به صورت دقیق مشخص نیست. همچنین، ابعاد درون‌زا برای هر بعد تاکنون تعیین نشده است. افزون بر این، تأثیر متقابل متغیرهای برون‌زا با لحاظ تأثیر متغیرهای درون‌زا مورد بررسی قرار نگرفته است. بنابراین، این مطالعه به دنبال رفع نیاز ذینفعان و تصمیم‌گیران این حوزه جهت اخذ اطلاعات حسابداری باکیفیت است. با توجه به اهمیت بانک‌ها در اقتصاد کشور و سنجه‌های کیفیت سود و عدم تقارن اطلاعاتی در این صنعت خاص، هدف پژوهش بررسی تأثیر متقابل کیفیت سود و عدم تقارن اطلاعاتی در صنعت بانکداری است. به منظور بررسی دقیق‌تر از سیستم معادلات هم‌زمان استفاده می‌شود.

در مطالعات پیشین، رابطه یک‌طرفه بین کیفیت سود و عدم تقارن اطلاعاتی، در نظر گرفته شده است در حالی که با توجه به مطالب ذکر شده در بالا، این رابطه دو طرفه است و باید به شیوه هم‌زمان این رابطه دو طرفه مورد آزمون قرار گیرد. این پژوهش متغیرهای مناسب درون‌زا را برای هر سنجه برون‌زا مشخص می‌سازد، به طوری که تأثیر متغیرهای درون‌زا بر برون‌زا را نمایان سازد. دیگر موردی که این مطالعه را به طور کامل از مطالعات پیشین متمایز می‌سازد، نحوه بررسی تأثیر متغیرهای کیفیت سود و عدم تقارن اطلاعاتی است که تأثیر متغیرهای درون‌زا را هم‌زمان بر این رابطه مورد سنجش قرار می‌دهد. بنابراین، این پژوهش در صدد بررسی تأثیر متقابل و هم‌زمان عدم تقارن اطلاعاتی و کیفیت سود با استفاده از معادلات هم‌زمان در صنعت بانکداری است تا شکافی که در مطالعات پیشین است را برطرف نماید و تأثیر این دو عامل به گونه دقیق‌تر مورد واکاوی قرار گیرد. افزون بر این، این پژوهش تاکنون در صنعت بانکداری انجام نشده است. بنابراین، این پژوهش بدیع است و به دنبال بسط دانش حسابداری در خصوص صنعت بانکداری است. این پژوهش به دنبال پاسخ به این پرسش‌هاست که آیا در شرایطی که عدم تقارن اطلاعاتی بر کیفیت سود تأثیر می‌گذارد به شکل متقابل و کیفیت سود نیز بر عدم تقارن اطلاعاتی تأثیر دارد؟ جهت تأثیر دوطرفه چگونه است؟ هدف این پژوهش پاسخ به پرسش‌های مطرح شده است.

به منظور نیل به اهداف پژوهش، در ابتدا مبانی نظری مربوط به عدم تقارن اطلاعاتی و کیفیت سود مطرح می‌شود. پس از بیان پیشینه مطالعه، الگو، روش‌شناسی، جامعه و نمونه آماری پژوهش ارائه می‌شود. پس از تشریح متغیرها، آمار توصیفی، نتایج آزمون فرضیه‌ها، بحث و نتیجه‌گیری و پیشنهادهای پژوهش بیان می‌شود.

مبانی نظری

عدم تقارن اطلاعاتی

گردآوری، تأمین و توزیع متناسب و عادلانه منابع مالی محدود بین افراد جامعه معیاری برای توسعه و پیشرفت اقتصاد هر کشوری است. مؤسسات مالی همچون بانک‌ها در این امور جایگاه مهم و نقش پررنگ واسطه‌گری مالی را عهده‌دار هستند. از این رو نقش شفافیت اطلاعات این صنعت در جامعه بسیار حائز اهمیت است. در این راستا، عدم تقارن اطلاعاتی یکی از مباحث مهم است. باتاچاریا و همکاران، (۲۰۱۲) حدود عدم تقارن اطلاعاتی را یک سفارش خرید یا فروش خاص ناشی از وجود یک سرمایه‌گذار با اطلاعات خصوصی تعریف کردند.

عدم تقارن اطلاعاتی را می‌توان متأثر از تئوری بازارگردانی دانست. طبق این تئوری، که این افراد بین دو گروه معامله‌گر در بازار سرمایه قرار می‌گیرند. گروه اول شامل سرمایه‌گذارانی است که اطلاعات بیشتری نسبت به بازارگردان دارد و اگر معامله‌ای بین آنان رخ دهد، بازارگردان متضرر می‌شود چرا که سرمایه‌گذار آگاه تنها در مواردی با او وارد معامله می‌شود که قیمت‌های اعلام شده نسبت به اطلاعات آنان مطلوب باشد. گروه دوم سرمایه‌گذاران به اصطلاح کم اطلاع هستند که نقدینگی بالا یا نیاز شدید به نقدینگی دارند. بازارگردان در معامله با اینگونه افراد، زیان ناشی از معامله با گروه اول را به وسیله کسب سود ناشی از داشتن اطلاعات بیشتر جبران می کند. درنهایت توازن بین سود و زیان ذکر شده، بازار خرید و فروش را ایجاد می کند.

طبق مطالعه اسکات و اوبریان[5] (۲۰۰۳) که از تئوری نمایندگی نشأت می‌گیرد، یکی از پیامدهای ناشی از تضاد منافع میان سهامداران و مدیران، عدم تقارن اطلاعاتی است. عدم تقارن اطلاعاتی ناشی از تضاد منافع بین مدیر و مالک در بستر نظریه نمایندگی ایجاد می‌شود (حساس‌یگانه و خیرالهی، ۱۳۸۷). بر اساس الگوی جنسن و مکلینگ[6]، (۱۹۷۶)، یکی از مشکلات نمایندگی، ناتوانی سهامدار در پیگیری روزانه اقدامات مدیر است. بنابراین، سهامدار اطلاعات لازم درمورد عملیات مدیر را ندارد و این حالت عدم تقارن اطلاعات نامگذاری شده است، به این معنی که اطلاعات اضافی مدیر که اطلاعات خصوصی تعریف می‌شود، در اختیار مالک نیست (نمازی، ۱۳۸۴).

طبق نظریه نمایندگی زمانی که فعالیت بنگاه‌های اقتصادی گسترده‌تر می‌شود، برای اداره بهتر امور، طی قراردادی بین مدیر و مالک، اختیارات از مالک به مدیر تفویض می‌شود (جنسن و مکلینگ، ۱۹۷۶). طبق این نظریه، اگر در این قرارداد، به تمام جوانب و منافع دو طرف توجه نشود، مدیران می‌توانند با اطلاعات خود و با استفاده از اطلاعات درون سازمانی که در دسترس سرمایه‌گذاران و اعتباردهندگان نیست، با دستکاری صورت‌های مالی و سایر گزارش‌های غیرمالی، استفاده‌کنندگان را گمراه کنند. پس می‌توان در نظر داشت که در شرایط عدم تقارن اطلاعاتی دستکاری‌های گزارش‌های مالی توسط مدیر، کیفیت سود نیز از این شرایط متأثر شود. با توجه به مطالب بیان شده، فرضیه اول به شرح زیر ارائه می‌شود:

فرضیه اول: عدم تقارن اطلاعاتی بر کیفیت سود تأثیر منفی معنادار دارد.

کیفیت سود

سود در زمره مهمترین اطلاعات حسابداری است که همواره مورد توجه گروه های مختلف استفاده کننده قرار گرفته است. به واسطه سود واحد تجاری، ارزیابی دورنمای جریان‌های نقدی سرمایه‌گذاری‌ها یا وام‌های اعطایی انجام می‌شود (فرانسیس و همکاران، ۲۰۰۴). عبارت کیفیت سود به توانایی مدیران در استفاده از اقلام اختیاری از جمله، اصول یا استانداردهای حسابداری، روش‌های برآورد و زمان‌بندی معاملات در اندازه‌گیری و گزارشگری سود اشاره دارد (سلیمانی‌امیری و همکاران، ۱۳۹۷).

عدم تقارن اطلاعات میان مدیریت و افراد برون سازمانی نظیر سرمایه‌گذاران و اعتباردهندگان فرصتی را برای مدیر فراهم می‌کند که با ابزارهایی مانند اقلام تعهدی اختیاری، رقم سود دستکاری شود و کیفیت سود متأثر از این رویداد باشد (باتاچاریا و همکاران، ۲۰۱۲). سود گزارش شده از شرایط مالی واقعی واحد اقتصادی فاصله گرفته و کیفیت محتوای سود تحت تأثیر قرار می‌گیرد در نتیجه سرمایه‌گذاران، اعتباردهندگان، قانون‌گذاران، مشتریان و رقبا طبق سود گزارش شده با کیفیت پایین، ممکن است تصمیمات نادرستی اتخاذ نمایند (رضازاده و آزاد، ۱۳۸۷). با توجه به مطالب بیان شده، فرضیه دوم به شرح زیر ارائه می‌شود:

فرضیه دوم: کیفیت سود بر عدم تقارن اطلاعاتی تأثیر منفی معنادار دارد.

با توجه به مبانی نظری ارائه شده، در بانک‌های پذیرفته شده در بورس اوراق بهادار تهران و فرابورس ایران، کیفیت سود بر عدم تقارن اطلاعاتی تأثیر دارد. همچنین، عدم تقارن اطلاعاتی نیز، بر کیفیت سود تأثیر دارد. بنابراین، با توجه به تأثیر متقابل این دو متغیر بر یکدیگر، این پژوهش به دنبال بررسی تأثیر هم‌زمان و متقابل کیفیت سود و عدم تقارن اطلاعاتی با استفاده از سیستم معادلات همزمان است تا شکافی که در مطالعات پیشین است را برطرف نماید و تأثیر این دو عامل به گونه دقیق‌تر مورد واکاوی قرار گیرد. افزون بر این، این پژوهش تاکنون در صنعت بانکداری انجام نشده است. بنابراین، مطالعه این تأثیر با توجه به اهمیت سیستم بانکی در هر کشور، حائز اهمیت است. با توجه به مطالب بیان شده، فرضیه سوم به شرح زیر ارائه می‌شود:

فرضیه سوم: کیفیت سود و عدم تقارن اطلاعاتی برهم تأثیر متقابل و هم‌زمان دارند.

پیشینه پژوهش

پیشینه مطالعاتی درمورد رابطه دو متغیر عدم تقارن اطلاعاتی و کیفیت سود در صنعت بانکداری اندک است، سایر پیشینه‌های مرتبط با ارزیابی متغیرهای پژوهش در شرکت‌های پذیرفته شده در بورس اوراق بهادار تهران در ادامه مطرح می‌شود. باتاچاریا و همکاران[۷] (۲۰۱۰) رابطه کیفیت سود و عدم تقارن اطلاعاتی را بررسی کردند. نتایج پژوهش آنان نشان داد که کیفیت پایین سود موجب افزایش عدم تقارن اطلاعاتی در بازارهای مالی می‌شود. کورمیر و همکاران[۸] (۲۰۱۳) درپژوهشی به بررسی تأثیر افشای اختیاری بر رابطه بین کیفیت سود و عدم تقارن اطلاعاتی پرداختند. یافته‌های آن‌ها نشان داد که کیفیت بالای سود و افشای اختیاری هردو باعث کاهش عدم تقارن اطلاعاتی می‌شود.

دی[9] (۲۰۱۷) به صورت تحلیلی نشان داد که وجود عدم تقارن اطلاعاتی بین مدیریت سود و سهامداران یک شرط اساسی برای مدیریت سود است. وی فرض کرد که بین گروههای سهامداران همپوشانی وجود دارد. سهامداران فروشنده به مدیریت اجازه می دهند که به منظور القای یک تصویر مناسب به گروه خریداران از یک سیاست مشخص مدیریت سود پیروی نماید. در این الگو، مدیر از یک مزیت اطلاعاتی نسبت به سهامداران برخوردار است. در نتیجه عدم تقارن اطلاعاتی شرط ضروری برای مدیریت سود در این وضعیت است. ترن و همکاران[10] (۲۰۱۹) به بررسی رابطه بین مدیریت سود و تنوع عملکرد بانکی در بازه زمانی ۲۰۱۵-۲۰۰۱ پرداختند. نتیجه پژوهش آنان بیانگر وجود رابطه مثبت و معنادار بین مدیریت سود و تنوع عملکرد بانکها بود. همچنین متفاوت بودن عملکرد بانک‌ها، عدم تقارن اطلاعاتی را افزایش می‌دهد و تأثیر تنوع عملکرد بانکی در دوران بحرانی بر مدیریت سود کمتر است. هوساین و هوساین[11] (۲۰۲۰) تأثیر کیفیت سود را بر هزینه بدهی در شرکت‌های فرانسوی طی بازه زمانی ۲۰۱۵-۲۰۰۵ مورد بررسی قرار دادند. آنان دریافتند که کیفیت سود تأثیر منفی معنادار بر هزینه بدهی دارد.

باباجانی و همکاران (۱۳۹۳) رابطه بین عدم تقارن اطلاعاتی و مدیریت سود را بررسی کردند. نتایج پژوهش نشان داد که شاخص عدم تقارن اطلاعاتی بر میزان مدیریت سود تأثیر مثبت و معناداری دارد. ثقفی و همکاران (۱۳۹۵) به بررسی رابطه کیفیت سود و عدم تقارن اطلاعاتی در شرکت‌های پذیرفته شده در بورس اوراق بهادار تهران پرداختند. آنان دریافتند که سطح عدم تقارن اطلاعاتی با افزایش یا کاهش کیفیت سود رابطه ندارد، ولی عدم تقارن اطلاعاتی در دوره زمانی پس از اعلام سود نسبت به قبل از آن افزایش می‌یابد. مشکی و همکاران (۱۳۹۷) با مطالعه استراتژی مدیریت، رقابت بازار و کیفیت سود را در بازه ۱۳۹۴-۱۳۸۹ به این نتیجه رسیدند که استراتژی مدیریت بر کیفیت سود تأثیر دارد. میزان این گرایش نیز بسیار بااهمیت است.

قوسی (۱۳۹۸) در پژوهشی مدیریت سود واقعی بر محتوای اطلاعاتی سود با تأکید بر عدم تقارن اطلاعاتی در شرکت‌های پذیرفته شده در بورس اوراق بهادار تهران را بررسی کردند. طبق نتایج پژوهش محتوای اطلاعاتی سود بر مدیریت سود واقعی تأثیر منفی و معنی دار دارد. همچنین عدم تقارن اطلاعاتی بر محتوای اطلاعاتی سود تأثیر معنی دار دارد ولی مدیریت سود واقعی با عدم تقارن اطلاعاتی بر محتوای اطلاعاتی سود تاثیری ندارد. داداشی و نوروزی (۱۳۹۹) رابطه بین کیفیت سود و هزینه سرمایه را مورد بررسی قرار دادند. نتایج پژوهش آن‌ها نشان داد که بین این دو متغیر رابطه معنادار وجود دارد.

روش‌شناسی و الگوی مفهومی پژوهش

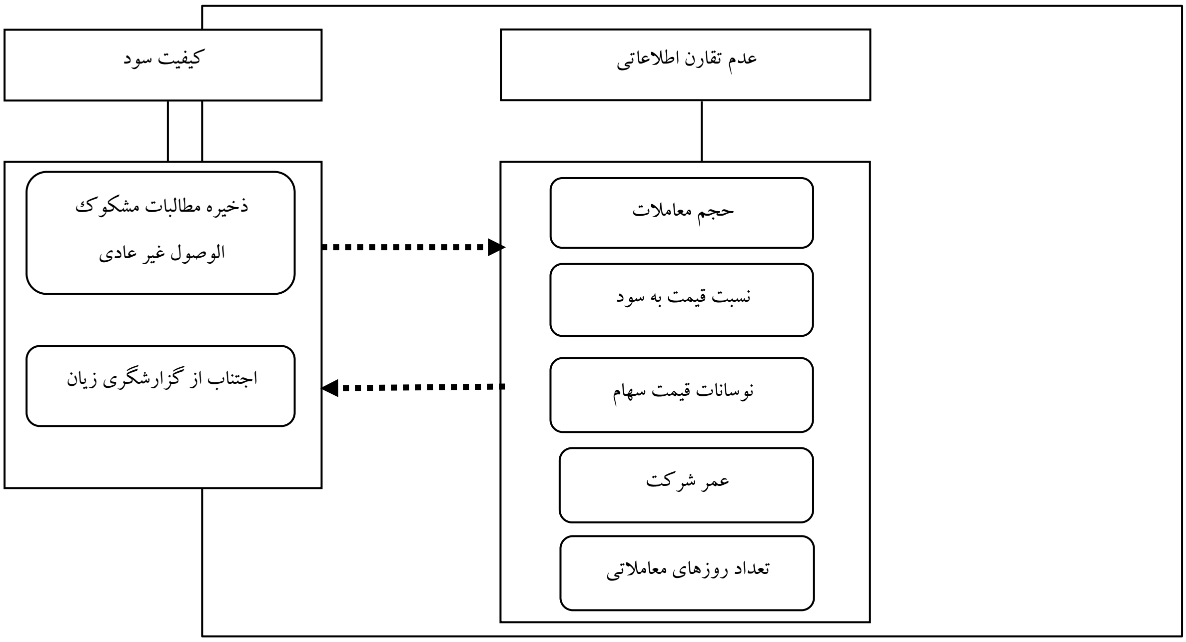
این پژوهش از حیث هدف یک پژوهش کاربردی است. هم‌چنین، پژوهش حاضر از دسته پژوهش‌های توصیفی، کمّی و پس‌رویدادی است که از روش علمی ساخت و اثبات تجربی استفاده می‌کند و بر اساس فرضیه‌ها و طرح‌های پژوهش از قبل تعیین شده انجام می‌شود. از این دسته پژوهش‌ها زمانی استفاده می‌شود که معیار اندازه‌گیری داده‌ها کمّی است و برای استخراج نتیجه‌ها از فن‌های آماری استفاده می‌شود (نمازی، ۱۳۸۲). برای تدوین متون و ادبیات پژوهش از مطالعات کتابخانه‌ای استفاده می‌شود که در برگیرنده کتب، پایان‌نامه‌ها، و نشریات تخصصی فارسی و انگلیسی و هم‌چنین پایگاه‌های الکترونیکی است. برای گردآوری داده‌های موردنیاز برای انجام این پژوهش از صورت‌های مالی

بانک‌های پذیرفته شده در بورس اوراق بهادار تهران و فرابورس ایران، موجود در سایت کدال، نرم‌افزار ره‌آورد نوین و همچنین از ترازنامه بانک‌ها، و همچنین از اطلاعات بازار سهام آنها استفاده شد.

در پژوهش حاضر برای آزمون فرضیه پژوهش براساس داده‌های بدست آمده از آمار توصیفی، بررسی پایایی متغیرهای پژوهش، بررسی اثرات متغیرهای مورد مطالعه، آزمون‌های استنباطی و آزمون‌های تأیید کننده با استفاده از نرم‌افزارهای ایویوز برای آمار توصیفی و آزمون نرمال بودن و علیت دوطرفه گرنجری و Smart PLS نسخه ۲ برای مدل یابی معادلات ساختاری و تحلیل مسیر و برازش مدل انجام شده است.

الگوی مفهومی پژوهش

با توجه به مبانی نظری پژوهش، الگوی مفهومی پژوهش تدوین شده است. شکل ۱، الگوی مفهومی پژوهش را نشان می‌دهد. در این الگو چگونگی تأثیر متقابل متغیرهای درون‌زا و همچنین برون‌زای پژوهش نشان داده شده است.



شکل ۱. نحوه رابطه و تأثیر متغیرهای پژوهش

طبق شکل ۱، با استفاده از تئوری بازارگردانی، طبق پژوهش باباجانی و همکاران (۱۳۹۳)، با استفاده از ترکیب پنج سنجه حجم معاملات، نوسان قیمت سهام، نسبت قیمت به سود (P/E)، تعداد روزهای معاملاتی و عمر شرکت شاخصی برای اندازه‌گیری عدم تقارن اطلاعاتی در نظر گرفته می‌شود. کیفیت سود نیز مطابق با شاخص دستکاری ذخیره مطالبات مشکوک‌الوصول تسهیلات (LLP[12]) و الگوی زین‌الدین و لئو[13] (۲۰۱۸)، با استفاده از دو شاخص اجتناب از گزارشگری زیان و ذخیره مطالبات مشکوک‌الوصول غیرعادی ارزیابی می‌شود.

شایان ذکر است که در این الگو، با فرض وجود رابطه و تأثیر متقابل متغیرهای کیفیت سود و عدم تقارن اطلاعاتی، متغیرهای کنترلی که اندازه بانک‌ها و سپرده بانکی است، به طور هم‌زمان بر متغیرهای مستقل و وابسته (که نقش آن‌ها به دلیل علیت متقابل جا به جا می‌شوند، یعنی در حالت اول عدم تقارن اطلاعاتی متغیر وابسته و کیفیت سود متغیر مستقل و در حالت دوم عدم تقارن اطلاعاتی متغیر مستقل و کیفیت سود متغیر وابسته است) تأثیر می‌گذارند.

اندازه‌گیری متغیرهای پژوهش

این پژوهش به بررسی تأثیر متقابل کیفیت سود بر عدم تقارن اطلاعاتی در صنعت بانکداری با استفاده از معادلات هم‌زمان می‌پردازد. در معادلات هم‌زمان، کیفیت سود به عنوان متغیر مستقل و عدم تقارن اطلاعاتی به عنوان متغیر وابسته و بار دیگر کیفیت سود متغیر وابسته و عدم تقارن اطلاعاتی متغیر مستقل درنظرگرفته می‌شود. هر کدام از این دو متغیر با کمک متغیرهای برون‌زا ارزیابی می‌شوند. در ادامه نحوه اندازه‌گیری هر کدام از متغیرهای درون‌زا (کیفیت سود و عدم تقارن اطلاعاتی) و متغیرهای برون‌زا در پژوهش حاضر بیان می‌شود.

عدم تقارن اطلاعاتی

در این پژوهش طبق مطالعه باباجانی و همکاران (۱۳۹۳) از پنج سنجه حجم معاملات، نوسان قیمت سهام، نسبت قیمت به سود (P/E)، تعداد روزهای معاملاتی و عمر شرکت برای اندازه‌گیری عدم تقارن اطلاعاتی استفاده می‌شود. سپس با ترکیب این پنج سنجه یک شاخص کلی[۱۴] محاسبه می‌شود.

به‌منظور ساخت شاخص ترکیبی، ابتدا رتبه چارکی بانک‌ها برای تمام سنجه‌های پنج‌گانه محاسبه می‌شود، به‌طوری که رتبه بالاتر در هر سنجه، به معنی درجه بالاتر عدم تقارن اطلاعاتی باشد. سپس رتبه‌های مربوط به هریک از آن‌ها در مورد هر یک با یکدیگر جمع می‌شود. بنابراین، میزان ارزش هر شاخص می‌تواند از ۵ تا ۲۵ باشد که هر چه این عدد بزرگ‌تر باشد، میزان عدم تقارن اطلاعاتی بیشتر خواهد بود.

حجم معاملات: به مجموع کل سهام مبادله شده بانک در یک دوره زمانی معین اطلاق می‌شود. طبق الگوی زین‌الدین و لئو (۲۰۱۸)، بانک‌های دارای حجم معاملات بالاتر، نوسان بیشتری در بازدهی سهام خود دارند که این امر در نهایت منجر به عدم تقارن اطلاعاتی بیشتر می‌شود.

نوسان قیمت سهام: به پراکندگی در بازدهی روزانه سهام طی سال مورد بررسی، اطلاق می‌شود. طبق مطالعات کورمیر و همکاران (۲۰۱۳) نوسانات قیمت سهام و عدم تقارن اطلاعاتی رابطه معکوس دارند، بنابراین، انتظار می‌رود هرچقدر سرمایه‌گذاران با سطح بالاتری از عدم تقارن اطلاعاتی مواجه باشند، احتمال پیش‌بینی غیردقیق بازده سهام توسط آن‌ها بیشتر باشد.

نسبت قیمت به سود (P/E): حاصل تقسیم قیمت سهام به سود هر سهم و بیانگر فرصت‌های رشد بانک است. انتظار می‌رود بانک‌ها با فرصت رشد بیشتر، سطح عدم تقارن اطلاعاتی بالاتری داشته باشند.

تعداد روزهای معاملاتی: تعداد روزهایی که در سال، سهام بانک‌ها معامله شده است. انتظار می‌رود سطح عدم تقارن اطلاعاتی بانک‌ها با کاهش تعداد روزهای توقف نماد بانک‌ها و افزایش حجم معاملات آن‌ها، کاهش یابد.

عمر شرکت: به زمان پذیرش در بورس اطلاق می‌شود. انتظار می‌رود هرچه سال‌های بیشتری از زمان حضور در بازار سرمایه گذشته باشد، اطلاعات بیشتری از بانک وجود داشته باشد، از این رو می‌توان گفت عمر بانک با عدم تقارن اطلاعاتی رابطه معکوس دارد (و لئو، ۲۰۱۸).

کیفیت سود

از آنجا که کیفیت سود به طور مستقیم قابل اندازه‌گیری نیست، روش‌های برآورد آن در صنعت بانکداری طبق مطالعه ترن و همکاران (۲۰۱۹) با تمرکز بر مفهوم دستکاری ذخیره مطالبات مشکوک‌الوصول تسهیلات است. مفهوم مطالبات مشکوک الوصول از مهم‌ترین مفاهیم اقلام تعهدی در بانک‌ها است و نشان دهنده عدم تقارن اطلاعاتی است، زیرا به قضاوت ذهنی مدیران بستگی دارد (بیتی و لیائو[15]، ۲۰۱۴). از بین الگوهای ارزیابی کیفیت سود در صنعت بانکداری، الگوی استفاده شده توسط زین‌الدین و لئو (۲۰۱۸) در این پژوهش استفاده می‌شود. در این الگو علاوه بر تمرکز بر مفهوم ذخیره مطالبات مشکوک‌الوصول از مفهوم اجتناب از گزارشگری زیان نیز استفاده می‌شود و با استفاده از این دو شاخص کیفیت سود ارزیابی می‌شود.

در این الگو، برای سنجش کیفیت سود، اقلام تعهدی به دو دسته تقسیم می‌شوند؛ دسته اول شامل اقلام تعهدی است که مدیریت نسبت به آن‌ها دارای اختیار عمل است و می‌توان از آن‌ها برای کیفیت سود استفاده نمود. دسته دوم شامل اقلام تعهدی است که مدیریت فاقد اختیار دخل و تصرف در وضعیت آن‌ها است. در صنعت بانکداری، در اکثر مواقع تحلیل دو مرحله‌ای با توجه به مطالبات مشکوک الوصول ناشی از تسهیلات بانکی برای موشکافی کیفیت سود انجام می‌شود. در این روش، در مرحله نخست، بخش تحت کنترل (احتیاطی) حساب‌های تعهدی از بخش خارج از کنترل جدا می‌شود. در حقیقت در مرحله نخست، بخش ذخیره مطالبات مشکوک‌الوصول الگوسازی می‌شود و ارزش‌های باقیمانده ایجاد شده در این مرحله که معادل با بخش احتیاطی یا تحت کنترل تلقی می‌شوند، در مرحله دوم به عنوان متغیر وابسته در نظر گرفته می‌شوند. در این مطالعه دو معیار برای سنجش کیفیت سود وجود دارد، زیرا پدیده کیفیت سود یک سنجه چند بعدی است و استفاده از یک معیار به طور مناسب و جامع تمام ابعاد احتمالی آن را در برنمی‌گیرد. این دو سنجه در مطالعات گذشته به‌عنوان معیارهای مطمئن و معتبر نشان داده شده‌اند (زین الدین و لئو، ۲۰۱۸). در ادامه این دو سنجه تشریح می‌شوند.

ذخیره مطالبات مشکوک‌الوصول غیرعادی: به دلیل قابل توجه بودن مطالبات مشکوک الوصول در صنعت بانکداری و اختیار عمل مدیران در اندازه‌گیری آن به‌عنوان یکی از معیارهای کیفیت سود استفاده می‌شود. در رابطه (۱) نحوه اندازه‌گیری این متغیر نشان داده می‌شود.

$$ALLP_{it} = \alpha_0 + \alpha_1 LCO_{it} + \alpha_2 LLA_{it} + \alpha_3 \Delta NPL_{it} + \alpha_4 EBITP_{it} + \varepsilon_{it} \qquad (۱)$$

$ALLP_{it}$: ذخیره مطالبات مشکوک الوصول غیر عادی بانک‌ها برای سال **t**،

LCO_{it}: خالص وام‌های سوخت شده در سال **t**،

LLA_{it}: مقدار مجاز یا ذخیره مطالبات مشکوک الوصول بانک‌ها در پایان سال **t-۱**،

ΔNPL_{it}: تغییرات در وام‌های سررسید گذشته بانک‌ها در سال **t** نسبت به سال **t-۱**،

$EBITP_{it}$: سود قبل از مالیات و ذخیره مطالبات مشکوک الوصول بانک‌ها برای سال **t**.

تمامی متغیرها در این رابطه برحسب دارایی‌های ابتدای دوره هم مقیاس می‌شوند. همچنین، در این رابطه جزء باقی‌مانده رگرسیون به‌عنوان معیار سنجش کیفیت سود در نظر گرفته می‌شود.

اجتناب از گزارشگری زیان: در این متغیر ابتدا نموداری از سود هم‌مقیاس شده (سود قبل از مالیات تقسیم بر کل دارایی‌ها) تهیه و میزان دامنه نوسان آن بررسی می‌شود. در شرایط عدم مدیریت سود، انتظار می‌رود که این نمودار ویژگی نرمال بودن و تقارن بیشتری داشته باشد و به بیان دیگر کیفیت سود بالاتری داشته باشند. طبق پژوهش زین‌الدین و لئو (۲۰۱۸) در صورتی که رقم سود هم‌مقیاس شده بین صفر و ۰/۱۵ در هر دوره باشد، عدد یک و در غیر این صورت عدد صفر برای هر بانک به عنوان شاخصی از کیفیت سود در نظر گرفته می‌شود. عدد یک به معنی کیفیت سود کمتر و عدد صفر به معنی کیفیت سود بیشتر است.

متغیرهای کنترلی

پژوهش حاضر براساس مطالعه ثقفی و همکاران (۱۳۹۵) اندازه و سپرده بانکی به‌عنوان متغیرهای کنترلی در نظر گرفته شده و نحوه محاسبات آنها به صورت زیر است:

اندازه بانک: لگاریتم طبیعی مجموع درآمدها،

سپرده بانکی: حاصل تقسیم جمع کل سپرده‌ها به کل دارایی‌های اول دوره.

جدول ۱، تعریف و اندازه‌گیری متغیرهای پژوهش را نشان می‌دهد.

جدول ۱. تعریف و اندازه‌گیری متغیرهای پژوهش

نام متغیر	نماد انگلیسی	تعریف عملیاتی
پنج شاخص برای اندازه‌گیری عدم تقارن اطلاعاتی (ASSEMETRY)		
حجم معاملات	Turnover	جمع کل سهام مبادله شده بانک در یک دوره زمانی معین
نوسان قیمت سهام	Stock price fluctuations	پراکندگی در بازدهی روزانه سهام طی سال مورد بررسی
نسبت قیمت به سود	P/E	حاصل تقسیم قیمت سهام به سود هر سهم
تعداد روزهای معاملاتی	Trading day	کل روزهای فعالیت در بورس و فرابورس منهای تعداد روزهای توقف نماد بانک‌ها
عمر بانک	Bank life	مدت زمان پذیرش بانک در فرابورس و بورس
دو شاخص برای اندازه‌گیری کیفیت سود (EQUALITY)		
ذخیره مطالبات مشکوک الوصول غیر عادی بانک‌ها برای سال **t**	ALLP	به شرح رابطه شماره ۱
اجتناب از گزارشگری زیان	ARL	در صورتی که رقم سود هم‌مقیاس شده بین صفر و ۰/۱۵ در هر دوره باشد، عدد یک و در غیر این صورت عدد صفر قرار داده می‌شود.
متغیرهای مربوط به محاسبه ALLP		
خالص وام‌های سوخت شده در سال **t**	LCO	میزان وام سوخت شده در هر سال
مقدار مجاز یا ذخیره مطالبات مشکوک الوصول بانک‌ها در پایان سال **t-1**	LLA	ذخیره مطالبات مشکوک‌الوصول برای تسهیلاتی است که بیش از ۱۸ ماه از سررسید آن‌ها گذشته است.
تغییرات در وام‌های سررسید گذشته بانک‌ها در سال **t** نسبت به سال **t-1**	NPL	تسهیلاتی است که از سررسید آن بین ۲ تا ۶ ماه گذشته است.
سود قبل از مالیات و ذخیره مطالبات مشکوک‌الوصول بانک‌ها برای سال **t**.	EBITP	سود خالص به علاوه مالیات و ذخیره مطالبات مشکوک‌الوصول
متغیرهای کنترلی		
اندازه بانک	Size	لگاریتم طبیعی مجموع درآمدها
سپرده بانکی	Depo	حاصل تقسیم جمع کل سپرده‌ها به کل دارایی‌های اول دوره

جامعه و نمونه آماری پژوهش

جامعه آماری این پژوهش شامل ۲۳ بانک پذیرفته شده در بورس اوراق بهادار تهران و فرابورس ایران در دوره زمانی ۱۱ ساله شامل سال‌های ۱۳۹۷-۱۳۸۷ است. باتوجه به شرایط زیر، تعداد ۱۱ بانک برای آزمون فرضیه‌های پژوهش انتخاب شدند:

۱. بانک‌ها باید قبل از سال ۱۳۸۷ در بورس و فرابورس پذیرفته شده باشند و از ابتدای سال ۱۳۸۷ سهام آن‌ها در بورس و فرابورس معامله شود.

۲. به لحاظ افزایش قابلیت مقایسه، بانک‌ها باید پایان سال مالی آن‌ها منتهی به پایان اسفند ماه باشد.

۳. باید در فاصله زمانی ۱۳۸۷ تا ۱۳۹۷ تغییر سال مالی یا تغییر فعالیت نداده باشند.

۴. در دوره مورد بررسی توقف معامله قابل توجه نداشته باشند.

۵. دسترسی لازم به صورتهای مالی وجود داشته باشند.

معادله‌های رگرسیونی فرضیه‌های پژوهش

با توجه به پژوهش‌های اسکات و اوبریان (۲۰۰۳) و حساس‌یگانه و خیرالهی، (۱۳۸۷)، معادله رگرسیونی فرضیه اول به شرح رابطه (۲) است:

$$ASSYMETRY_{jt} = \beta_0 + \beta_1 EQUALITY_{jt} + \beta_2 Size_{jt} + \beta_3 DEPO_{jt} + \varepsilon_{jt} \qquad \text{(۲) رابطه}$$

طبق پژوهش فرانسیس و همکاران (۲۰۰۴)، معادله رگرسیونی فرضیه دوم پژوهش، به شرح رابطه (۳) است:

$$EQUALITY_{jt} = \beta_0 + \beta_1 ASSYMETRY_{jt} + \beta_2 Size_{jt} + \beta_3 DEPO_{jt} + \varepsilon_{jt} \qquad \text{(۳) رابطه}$$

با توجه به مبانی نظری و پیشینه پژوهش، پس از عدم‌رد فرضیه‌های اول و دوم پژوهش، فرضیه سوم مطالعه مبنی بر تبیین رابطه و تأثیر متقابل متغیرهای کیفیت سود و عدم تقارن اطلاعاتی، به گونه هم‌زمان انجام می‌شود. جهت آزمون فرضیه سوم، از آزمون علیت دوطرفه گرنجری استفاده شده است.

آمار توصیفی و ماتریس کوواریانس

به‌منظور شناخت بهتر ماهیت جامعه‌ای که در پژوهش، مطالعه قرار می‌شود و آشنایی بیش‌تر با متغیرهای پژوهش، قبل از تجزیه و تحلیل داده‌های آماری، لازم است این داده‌ها از نظر آمار توصیفی بررسی شود. جدول ۲ آمار توصیفی برای همه متغیرهای پژوهش را نشان می‌دهد.

جدول ۲. آماره‌های توصیفی متغیرهای پژوهش

آماره/ متغیر	میانگین	میانه	انحراف معیار	بیشینه	کمینه
شاخص عدم تقارن اطلاعاتی	۱۳/۷۳۶	۱۴/۰۰۰	۳/۷۰۸	۲۲/۰۰۰	۵/۰۰۰
شاخص ذخیره مطالبات مشکوک الوصول غیرعادی	-۰/۰۸۱	-۰/۰۲۶	۰/۲۶۹	۰/۳۳۲	-۱/۹۷۵
اجتناب از گزارشگری زیان	۰/۷۹۳	۱/۰۰۰	۰/۴۱۱	۱/۰۰۰	۰/۰۰۰
اندازه شرکت	۷/۰۰۸	۷/۰۰۶	۰/۵۶۹	۸/۰۱۲	۶/۰۲۱
نسبت سپرده بانکی	۰/۶۸۲	۰/۷۵۴	۰/۲۰۵	۰/۸۹۳	۰/۱۲۸

طبق این جدول با مقایسه اعداد آمار توصیفی مربوط به شاخص عدم تقارن اطلاعاتی، مشاهده می‌شود که میانگین شاخص مذکور ۱۳/۷۳۶ است که این امر بازگوکننده عدم تقارن اطلاعاتی به نسبت بالا در میان بانک‌ها است. در این

راستا، اعداد مرتبط با شاخص ذخیره مطالبات مشکوک الوصول غیرعادی و اجتناب از گزارشگری زیان با شاخص عدم تقارن اطلاعاتی همخوانی دارد. از سویی دیگر، میانگین نسبت سپرده بانکی با نمایش عدد ۰/۶۸۲ توضیح دهنده آن است که به طور میانگین مجموع سپرده‌های بانکی در حدود ۶۸/۲ درصد از مجموع کل دارایی‌های بانک‌ها است.

عامل تورم واریانس (VIF) برای ارزیابی شدت هم‌خطی چندگانه در تحلیل رگرسیون استفاده شده است. جدول ۳ این نتایج را نشان می‌دهد.

جدول ۳. عامل تورم واریانس VIF

متغیر	آماره VIF
شاخص عدم تقارن اطلاعاتی	۱/۰۰۷
شاخص ذخیره مطالبات مشکوک الوصول غیرعادی	۱/۰۴۷
اجتناب از گزارشگری زیان	۱/۰۲۹
اندازه شرکت	۱/۰۳۷
نسبت سپرده بانکی	۱/۰۳۳

اگر آماره آزمونVIF به یک نزدیک باشد نشان دهنده عدم وجود هم‌خطی است. در این بین، آماره VIF در جدول ۳ نشان‌دهنده عدم وجود هم‌خطی در بین الگوی مورد آزمون است.

یکی از مفروضات الگوهای رگرسیونی، نبود همبستگی بین متغیرهای توضیحی (مستقل و کنترلی) است. به منظور اطمینان از رعایت چنین فرضی، در پژوهش حاضر از مفهوم کوواریانس استفاده شده است. در صورت نبود رابطه، مقدار کوواریانس برابر با صفر(یا نزدیک به صفر) است و به اصطلاح به آن دو متغیر مستقل گفته می‌شود (لازم به ذکر است که کوواریانس یک متغیر با خودش، همان واریانس متغیر است).

جدول ۴. ماتریس کوواریانس متغیرهای پژوهش

متغیر	شاخص عدم تقارن اطلاعاتی	شاخص کیفیت سود	اندازه شرکت	نسبت سپرده بانکی
شاخص عدم تقارن اطلاعاتی	۱۳/۶۳۳	–	–	–
شاخص کیفیت سود	-۰/۰۱۰	۰/۱۶۸	–	–
اندازه شرکت	۰/۰۰۵	۰/۰۱۸	۰/۳۲۲	–
نسبت سپرده بانکی	۰/۰۰۶	۰/۰۰۳	۰/۰۱۹	۰/۰۴۲

جدول ۴ ماتریس کواریانس متغیرهای پژوهش را ارائه می‌دهد. با توجه به این جدول، همبستگی قابل ملاحظه‌ای که بتواند نتایج اجرای الگوها را دستخوش تغییراتی کند، مشاهده نشد.

آمار استنباطی

پایایی یا ایستایی متغیرهای پژوهش

قبل از برآورد الگو باید پایایی (ایستایی) متغیرهای مورد استفاده در الگو بررسی شود. مطابق با جدول شماره ۵ و با استفاده از آزمون لوین، لین و چو [16](LLC) در کلیه متغیرهای مستقل، وابسته، تعدیلی و کنترلی سطح معناداری در آزمون ریشه واحد (که باید کوچک‌تر از ۰/۰۵ باشد) نشان‌دهنده این است که تمامی متغیرهای پژوهش پایایی هستند.

جدول ۵. بررسی پایایی متغیرهای پژوهش

متغیر	آزمون لوین، لین و چو		نتیجه آزمون LLC
	آماره آزمون	سطح معناداری	پایایی متغیرهای پژوهش
شاخص عدم تقارن اطلاعاتی	۵/۴۰۷-	۰/۰۰۰	پایا
شاخص کیفیت سود	۱۷/۰۷۸-	۰/۰۰۰	پایا
اندازه شرکت	۴/۷۰۵-	۰/۰۰۰	پایا
نسبت سپرده بانکی	۳/۸۳۰-	۰/۰۰۰	پایا

اثبات درون‌زایی متغیرهای عدم تقارن اطلاعاتی و کیفیت سود

شرط لازم برای برآورد سیستم معادلات هم‌زمان اثبات درون‌زا بودن متغیرهای درون‌زای سیستم است. هر کدام از متغیرهای عدم تقارن اطلاعاتی و کیفیت سود به عنوان متغیر درون‌زای سیستم با استفاده از همه متغیرهای برون‌زای مربوطه با نرم‌افزار ایویوز برآورد و مقادیر باقی مانده به عنوان متغیر جداگانه (RES) درنظر گرفته می‌شود. سپس معادله مربوط به هرکدام از متغیرهای درون‌زای سیستم را با کمک تمام متغیرهای برون‌زا و متغیر جدید RES برآورد می‌شود.

طبق جدول ۶-الف و ۶-ب، به دلیل معنادار بودن ضرایب متغیر جدید RES، متغیر کیفیت سود در معادله عدم تقارن اطلاعاتی و برعکس متغیر عدم تقارن اطلاعاتی در معادله کیفیت سود درون‌زا است. پس رابطه متقابل این دو متغیر تأیید می‌شود.

جدول ۶-الف. آزمون درون‌زا بودن متغیر کیفیت سود

نام متغیر	ضریب	سطح معناداری
RES	۴۲/۳۰۲۱۴	۰/۰۰۰۰

جدول ۶-ب. آزمون درون‌زا بودن متغیر عدم تقارن اطلاعاتی

نام متغیر	ضریب	سطح معناداری
RES	۴۱/۰۸۱۴۱	۰/۰۰۰۰

آزمون علیت دوطرفه گرنجری

برای به‌دست آوردن شواهد بیشتر مبنی بر تأثیر دوطرفه بین دو متغیر کیفیت سود و عدم تقارن اطلاعاتی، ابتدا آزمون علیت گرنجر[۱۷] به‌کار می‌رود و چنانچه وجود رابطه علّی بین دو متغیر به روش تجربی نیز تأیید شد، آنگاه از سیستم معادلات هم‌زمان استفاده می‌شود. در این راستا، نتایج آزمون مندرج در جدول ۷ برای تأیید استفاده از معادلات هم‌زمان، لزوم استفاده از روش مذکور را تأیید کرده است. به عبارتی، با توجه به فرضیه‌های صفر این آزمون و مقادیر به دست آمده سطح معناداری، نتیجه بیانگر این است که فرضیه صفر رد می‌شوند و بنابراین، رابطه علّی دوطرفه بین دو متغیر یاد شده برقرار است.

جدول ۷. نتایج آزمون علیت دو طرفه گرنجری

آزمون علیت دو طرفه گرنجری			نتیجه آزمون علیت دو طرفه گرنجری
P-value	آماره F	فرضیه صفر	رد فرضیه صفر
۰/۰۰۷	۵/۲۵۹	کیفیت سود، علیت دو طرفه گرنجری عدم تقارن اطلاعاتی نیست.	کیفیت سود، علیت دو طرفه گرنجری عدم تقارن اطلاعاتی است.
۰/۰۰۰	۹/۱۹۸	عدم تقارن اطلاعاتی، علیت دو طرفه گرنجری کیفیت سود نیست.	عدم تقارن اطلاعاتی، علیت دو طرفه گرنجری کیفیت سود است.

تحلیل مسیر متغیرهای برون‌زای پژوهش

نتایج آزمون رابطه بین متغیرهای پنهان و آشکار مرتبط با الگوی ۱، در جدول ۸ نشان داده شده است.

جدول ۸. خلاصه نتایج آزمون رابطه بین متغیرهای پنهان و آشکار (الگوی ۱)

متغیر	ضریب	آماره t	نتیجه
حجم معاملات و عدم تقارن اطلاعاتی	۰/۳۳۷	۲/۶۸۲	عدم رد
نسبت قیمت به سود و عدم تقارن اطلاعاتی	۰/۲۲۴	۰/۳۵۸	رد
نوسانات قیمت سهام و عدم تقارن اطلاعاتی	۰/۰۵۲	۲/۳۲۰	عدم رد
عمر شرکت و عدم تقارن اطلاعاتی	۰/۳۳۹	۱/۹۸۸	عدم رد
تعداد روزهای معاملاتی و عدم تقارن اطلاعاتی	۰/۳۳۱	۳/۵۷۶	عدم رد
ذخیره مطالبات مشکوک الوصول غیرعادی و کیفیت سود	۰/۲۷۸	۲/۸۲۰	عدم رد
اجتناب از گزارشگری زیان و کیفیت سود	۰/۳۹۷	۳/۰۵۹	عدم رد

همان‌طور که در این جدول ملاحظه می‌شود، بر اساس نتایج به‌دست آمده متغیرهای حجم معاملات، نوسانات قیمت، عمر شرکت و تعداد روزهای معاملاتی با عدم تقارن اطلاعاتی به عنوان شاخص‌های توضیح‌دهنده رابطه مستقیم و معناداری دارند. از سویی، مشاهده می‌شود که متغیرهای ذخیره مطالبات مشکوک الوصول غیرعادی و اجتناب از گزارشگری زیان با کیفیت سود به عنوان شاخص‌های توضیح‌دهنده رابطه مستقیم و معناداری دارند.

همچنین، نتایج آزمون رابطه بین متغیرهای پنهان و آشکار مرتبط به الگوی ۲، در جدول ۹ (خلاصه نتایج آزمون رابطه بین متغیرهای پنهان و آشکار) نشان داده شده است. همان‌طور که در جدول ۹ ملاحظه می‌شود بر اساس نتایج به‌دست آمده متغیرهای حجم معاملات، نوسانات قیمت سهام، عمر شرکت و تعداد روزهای معاملاتی با عدم تقارن اطلاعاتی به عنوان شاخص‌های توضیح‌دهنده رابطه مستقیم و معناداری دارند. از سویی، مشاهده می‌شود که متغیرهای ذخیره مطالبات مشکوک الوصول غیرعادی و اجتناب از گزارشگری زیان با کیفیت سود به عنوان شاخص‌های توضیح‌دهنده رابطه مستقیم و معناداری دارند.

جدول ۹. خلاصه نتایج آزمون رابطه بین متغیرهای پنهان و آشکار (الگوی ۲)

متغیر	ضرائب	آماره t	نتیجه
حجم معاملات و عدم تقارن اطلاعاتی	۰/۳۰۴	۲/۷۰۶	عدم رد
نسبت قیمت به سود و عدم تقارن اطلاعاتی	۰/۲۶۷	۰/۴۰۸	رد
نوسانات قیمت سهام و عدم تقارن اطلاعاتی	۰/۱۱۷	۲/۳۱۱	عدم رد
عمر شرکت و عدم تقارن اطلاعاتی	۰/۳۹۱	۱/۹۷۳	عدم رد
تعداد روزهای معاملاتی و عدم تقارن اطلاعاتی	۰/۳۱۸	۳/۰۳۶	عدم رد
ذخیره مطالبات مشکوک الوصول غیرعادی و کیفیت سود	۰/۲۱۵	۲/۷۹۳	عدم رد
اجتناب از گزارشگری زیان و کیفیت سود	۰/۳۵۶	۳/۰۵۴	عدم رد

تحلیل مسیر متغیرهای درون‌زای پژوهش

در این راستا، با توجه به جدول ۸ و جدول ۹ (الگوی نهایی پژوهش) و جدول ۱۰- الف، مشاهده می‌شود که آماره t برای هر دو مسیر مد نظر (رابطه بین کیفیت سود و عدم تقارن اطلاعاتی و همچنین رابطه بین عدم تقارن اطلاعاتی و کیفیت سود)، به‌ترتیب ۲/۶۳۳- و ۲/۸۵۲- است. این آماره‌ها در سطح اطمینان ۹۹ درصد کلیه ضرایب رگرسیونی

مسیرها مطابق جدول ۱۰ معنادار است. از این رو، معیار GOF[۱۸] مربوط به بخش کلی معادلات ساختاری است. این معیار که با GOF نشان داده می‌شود، عددی بین صفر تا یک است و هرچقدر به یک نزدیک‌تر باشد، حکایت از برازش کلی بالاتر الگو دارد. آماره GOF برای الگوی مورد استفاده در الگوی ۱ و الگوی ۲ به ترتیب با مقدار ۰/۲۰۵ و ۰/۲۰۷ گویای برازش قابل قبول الگوی کلی پژوهش است.

جدول ۱۰-الف. برازش الگوهای مربوط به فرضیه‌های اول و دوم پژوهش

متغیر	ضرائب	آماره t	GOF	نتیجه
کیفیت سود و عدم تقارن اطلاعاتی	-۰/۳۳۸	-۲/۶۳۳	۰/۲۰۵	پذیرش
عدم تقارن اطلاعاتی و کیفیت سود	-۰/۳۴۲	-۲/۸۵۲	۰/۲۰۷	پذیرش

جدول ۱۰-ب. خلاصه آماره‌های مرتبط با الگوی پژوهش

متغیر	Q2	CR	AVE
شاخص عدم تقارن اطلاعاتی	۰/۲۹۲	۰/۷۰۴	۰/۵۸۶
شاخص کیفیت سود	۰/۵۶۲	۰/۷۲۶	۰/۵۰۷
اندازه شرکت	۱/۰۰۰	۱/۰۰۰	۱/۰۰۰
نسبت سپرده بانکی	۱/۰۰۰	۱/۰۰۰	۱/۰۰۰

سرانجام، با مشاهده جدول ۱۰- ب، مقدار شاخص واریانس استخراج شده (AVE) نیز، بیانگر اعتبار مناسب ابزارهای اندازه‌گیری است (این شاخص باید مقداری بیش از ۰/۵ داشته باشد). از سویی، شاخص قابلیت اعتبار مرکب[۱۹] سازه‌های اندازه‌گیری متغیرهای پژوهش، نشان‌دهنده اعتبار ترکیبی مناسب این متغیرها است (این شاخص باید مقداری بیش از ۰/۷ داشته باشد). همچنین، شاخص Q2 با نمایش اعداد مثبت برای تمامی رابطه‌ها، نشانگر کیفیت مناسب الگوی ساختاری برای تمامی مسیرهای پژوهش نیز است.

آزمون فرضیه‌های پژوهش

جدول ۱۱ نتایج حاصل از آزمون فرضیه پژوهش را با استفاده از معادلات ساختاری نشان می‌دهد. جدول‌های ۱۱-الف و ۱۱-ب این نتایج را برای هر فرضیه ارائه می‌نماید.

با توجه به جدول‌های بالا، مقدار آماره F در سطح کلیه بانک‌ها، که به ترتیب برابر با **۴/۸۹۴** و **۳/۳۳۳** است، الگو در سطح ۹۵ درصد معنادار است. افزون‌براین، با توجه به مقدار آماره دوربین واتسون که به ترتیب برابر با **۱/۸۶۳** و **۱/۸۰۵** است، وجود خود همبستگی پی‌درپی در اجزای اخلال رگرسیون رد می‌شود. مقدار R2adj به ترتیب برابر با **۰/۲۹۷** و **۰/۲۰۲** است. بنابراین، با توجه به این مقدار می‌توان در الگوی اول، ۲۹/۷ درصد از تغییرات متغیر وابسته (عدم تقارن اطلاعاتی) را به‌وسیله متغیرهای مستقل (کیفیت سود) و کنترلی (اندازه شرکت و نسبت سپرده بانکی) پیش‌بینی کرد. از سویی، با توجه به الگوی دوم، ۲۰/۲ درصد از تغییرات متغیر وابسته (کیفیت سود) را به‌وسیله متغیرهای مستقل (عدم تقارن اطلاعاتی) و کنترلی (اندازه شرکت و نسبت سپرده بانکی) پیش‌بینی کرد.

در نتیجه، طبق جدول ۱۱-الف، فرضیه اول پژوهش مبنی بر اینکه کیفیت سود بر عدم تقارن اطلاعاتی تأثیر دارد، پذیرفته می‌شود. سطح معناداری مربوط به متغیر کیفیت سود نشان‌دهنده آن است که کیفیت سود بر عدم تقارن اطلاعاتی تأثیر منفی و معناداری دارد. همچنین، طبق جدول ۱۱-ب، فرضیه دوم پژوهش مبنی بر اینکه عدم تقارن اطلاعاتی بر

کیفیت سود تأثیر دارد، پذیرفته می‌شود. سطح معناداری مربوط به متغیر عدم تقارن اطلاعاتی نشان‌دهنده آن است که عدم تقارن اطلاعاتی بر کیفیت سود تأثیر منفی و معناداری دارد.

جدول ۱۱. خلاصه نتایج آزمون فرضیه پژوهش

۱۱-الف. تأثیر کیفیت سود بر عدم تقارن اطلاعاتی.

مدل ۱: $\mathbf{ASSYMETRY_{jt} = \beta_0 + \beta_1 EQUALITY_{jt} + \beta_2 Size_{jt} + \beta_3 DEPO_{jt} + \varepsilon_{jt}}$

متغیر	ضرائب	خطای استاندارد	آماره **t**	سطح معناداری
کیفیت سود	۲/۶۵۹-	۰/۷۳۱	۳/۶۳۶-	۰/۰۰۰
اندازه شرکت	۰/۱۹۶	۰/۵۰۹	۰/۳۸۵	۰/۷۰۱
نسبت سپرده بانکی	۰/۱۵۰	۱/۴۲۸	۰/۱۰۵	۰/۹۱۶
مقدار ثابت	۱۲/۹۲۰	۳/۵۲۸	۳/۶۶۱	۰/۰۰۰
ضریب تعیین	ضریب تعیین تعدیل‌شده	آماره دوربین واتسن	آماره **F**	سطح معناداری
۰/۳۷۳	۰/۲۹۷	۱/۸۶۳	۴/۸۹۴	۰/۰۰۰

۱۱-ب. تأثیر عدم تقارن اطلاعاتی بر کیفیت سود.

مدل ۲: $\mathbf{EQUALITY_{jt} = \beta_0 + \beta_1 ASSYMETRY_{jt} + \beta_2 Size_{jt} + \beta_3 DEPO_{jt} + \varepsilon_{jt}}$

متغیر	ضرائب	خطای استاندارد	آماره **t**	سطح معناداری
عدم تقارن اطلاعاتی	۰/۰۲۳-	۰/۰۰۸	۳/۰۱۶-	۰/۰۰۳
اندازه شرکت	۰/۰۴۹	۰/۰۳۹	۱/۲۷۱	۰/۲۰۶
نسبت سپرده بانکی	۰/۱۵۵	۰/۱۰۳	۱/۵۱۲	۰/۱۳۳
مقدار ثابت	۰/۷۱۵	۰/۲۷۳	۲/۶۱۱	۰/۰۱۰
ضریب تعیین	ضریب تعیین تعدیل‌شده	آماره دوربین واتسن	آماره **F**	سطح معناداری
۰/۲۸۸	۰/۲۰۲	۱/۸۰۵	۳/۳۳۳	۰/۰۰۰

با توجه به آزمون علیت دو طرفه گرنجری مبنی بر تأثیر دو طرفه و هم‌زمان متغیرهای کیفیت سود و عدم تقارن اطلاعاتی و همچنین آزمون فرضیه‌ها مبنی بر تأثیر هر یک از این دو متغیر بر یکدیگر، نتیجه می‌شود که متغیرهای کیفیت سود و عدم تقارن اطلاعاتی بر یکدیگر، تأثیر متقابل و هم‌زمان دارند. در نتیجه فرضیه سوم پژوهش نیز پذیرفته می گردد.

بحث و نتیجه‌گیری

هدف از این پژوهش، بررسی تأثیر متقابل و هم زمان بین کیفیت سود بر عدم تقارن اطلاعاتی در صنعت بانکداری بود. اغلب پژوهش‌های پیشین تنها رابطه یک‌طرفه این دو متغیر را بررسی کرده‌اند. طبق مبانی نظری و پیشینه پژوهش‌های داخلی و خارجی تأثیر معنادار بین عدم تقارن اطلاعاتی بر کیفیت سود مستند شده است، حال در این پژوهش برخلاف سایر پژوهش‌های داخلی و خارجی تأثیر این دو متغیر به شکل متقابل و هم‌زمان، در جامعه آماری صنعت بانکداری بررسی نمود.

مهم‌ترین ریسک صنعت بانکداری ریسک اعتباری آنان است که ناشی از افزایش بدهی نسبت به سرمایه بانک‌هاست. نکته دیگر اینکه بخش اعظم دارایی بانک‌ها مطالبات ناشی از اعطای تسهیلات است، حال بسته به اینکه بازپرداخت مطالبات طی چه مراحل، سیاست و ابزارهای نظارتی بازپرداخت شود می تواند منجر به بی ثباتی بانک‌ها شود. مدیران در جهت منعکس نکردن شرایط عدم ثبات بانک ها ممکن است اقدام به مدیریت سود کنند که این اقدام آنان

کیفیت سود پایین را دربردارد و به دنبال آن سایر افراد فعال در بازار سرمایه از اطلاعات کامل و شفاف درون سازمانی محروم خواهند شد. این شرایط منجر به عدم تقارن اطلاعاتی را پیرامون صنعت بانکداری افزایش می‌دهد.

در این پژوهش با تحلیل داده‌های حاصل از آزمون فرضیه‌ها در سیستم معادلات همزمان یافته‌های فرضیه اول، نشان داد که کیفیت سود بر عدم تقارن اطلاعاتی تأثیر منفی و معنادار دارد. نتایج این پژوهش مشابه نتایج پژوهش‌های ثقفی و همکاران (۱۳۹۵)؛ باتاچاریا و همکاران (۲۰۱۰)؛ کورمیر و همکاران (۲۰۱۳) است. این پژوهشگران به این نتیجه رسیدند که کیفیت سود بر عدم تقارن اطلاعاتی تأثیر منفی و معنادار دارد. طبق یافته فرضیه دوم، عدم تقارن اطلاعاتی بر کیفیت سود تأثیر منفی و معنادار دارد. برخلاف نتایج مطالعات باباجانی و همکاران (۱۳۹۳) و آقایی و همکاران (۱۳۹۶)، کیفیت سود تأثیر منفی و معنادار بر عدم تقارن اطلاعاتی دارد. طبق یافته فرضیه سوم، این نتیجه حاصل شد که عدم تقارن اطلاعاتی و کیفیت سود در صنعت بانکداری به شکل متقابل و همزمان بر هم تأثیر منفی و معناداری دارند. به بیان دیگر در هر بانک اگر کیفیت سود بالا باشد باعث کاهش عدم تقارن اطلاعاتی می‌شود، همچنین اگر عدم تقارن اطلاعاتی در هر بانک افزایش یابد، کیفیت سود نیز در جهت معکوس کاهش می‌یابد.

پیشنهادهای پژوهش

پیشنهادهای کاربردی پژوهش

با توجه به نتیجه آزمون فرضیه اول پژوهش مبنی بر اینکه در صنعت بانکداری، کیفیت سود بر عدم تقارن اطلاعاتی تأثیر دارد، به سرمایه‌گذاران و اعتباردهندگان توصیه می‌شود به مفهوم کیفیت سود به عنوان یک مفهوم مهم حاصل از اطلاعات صورت‌های مالی توجه داشته باشند، زیرا با ارزیابی کیفیت سود بانکی می‌توانند از سطح عدم تقارن اطلاعاتی بین خود و افراد درون سازمانی مطلع شوند که این امر بر تصمیمات سرمایه‌گذاری و یا اخذ تسهیلات بانکی تأثیرگذار است.

از طرفی به دلیل نتیجه آزمون فرضیه دوم پژوهش مبنی بر تأثیر منفی عدم تقارن اطلاعاتی بر کیفیت سود، پیشنهاد می‌شود که کنترل و نظارت دقیق و سازمان‌یافته بر بانک‌ها برای انتشار اطلاعاتی مثل تحلیل‌های مدیریتی علاوه بر اطلاعات منتشر شده در صورت‌های مالی، اجرا شود، تا در این راستا شکاف اطلاعاتی بین افراد درون سازمانی و برون سازمانی کاهش یابد و استفاده‌کنندگان صورت‌های مالی بر اساس اطلاعات گزارش شده به شکل شفاف و قابل اتکا، تصمیم‌گیری کنند که یکی از اقلام گزارش شده سود با کیفیت بالا است.

پیشنهادهایی برای پژوهش‌های آتی

در این راستا، پیشنهاداتی برای پژوهش‌های آتی به شرح زیر مطرح می‌شود:

بررسی نقش تعدیلی متغیرهایی مانند: کیفیت افشا، کیفیت حسابرسی، ریسک نقدشوندگی، ریسک بازار، نسبت بدهی، ساختار سرمایه بر رابطه بین کیفیت سود و عدم تقارن اطلاعاتی در صنعت بانکداری.

بررسی رابطه متقابل کیفیت سود و عدم تقارن اطلاعاتی در دوره رکود و تورم اقتصادی در صنعت بانکداری.

بررسی رفتار جسورانه یا محافظه‌کارانه مدیران بر رابطه بین کیفیت سود و عدم تقارن اطلاعاتی در صنعت بانکداری.

محدودیت‌های پژوهش

برخی از این محدودیت‌ها در پژوهش حاضر به شرح زیر است:

با توجه به اینکه شکل ظاهری صورت‌های مالی بانک‌ها از سال ۱۳۸۷ تا به امروز یکسان سازی شده است، برخی اطلاعات مانند جزئیات ذخیره مطالبات سررسید گذشته یا سوخت شده در گزارش های مالی قبل از سال ۱۳۸۷ منتشر نشده بود. این امر در ارزیابی ذخیره مطالبات سررسید گذشته در سال‌های قبل از ۱۳۸۷ و در ادامه در الگوی ارزیابی کیفیت سود بانکی تأثیر داشت. همچنین برخی عوامل کلان اقتصادی هم چون عامل رکود و شرایط خاص بانک مرکزی در روند انجام پژوهش قابل کنترل نبود.

تقدیر و تشکر

از داوران گران‌قدر که با دقت نظر خود باعث ارتقای مقاله شدند، صمیمانه قدردانی می‌شود.

COVID-19 and Stock Market Reaction in Indonesia

Yanuar Trisnowati[1]* and Arianto Muditomo[2]

Abstract:
Research aims: COVID-19 Pandemic happens all over the world. Pandemic impact hits almost all elements of life, one of the affected real sectors is finance especially the stock market. This research is aimed to present the reaction of the equity market in Indonesia towards the COVID-19 pandemic
Design/Methodology/Approach: The research method that is used is the study to examine market reaction towards the pandemic and abnormal return around the occurrence by using two methods; mean-adjusted abnormal return and market model.
Research findings: From the research conducted over the 10 indicators of the stock market index in Indonesia, it is concluded that 8 industrial sectors that have tenacious reaction toward the COVID-19 pandemic hit in Indonesia, where it is also found that the agriculture sector; basic and chemical industry; miscellaneous, consumer goods; property and real estate; transport and infrastructure; finance; trade, service, and investment, give stronger reactions compared with mining and manufacture.
Theoretical contribution/Originality: Researches about the stock market reaction to the non-economy phenomenon have already been carried out, but the research that is specifically done to study sectoral index reaction towards the non-economy occurrences is still wide open to doing for deeper research.
Practitioner/Policy implication: This research can be important information for investors to understand the behavior of stock market efficiency in Indonesia in making decisions of investment
Research limitation/Implication: Non-economy event that becomes the subject of research is the COVID-19 pandemic that appeared and escalated fast all over the world. The researcher conducted the research and presented it as quickly as possible since the time is limited. It is meant to show a systematic and scientific thinking framework in addressing the non-economy events, but still in the context of reliability on the result of research to the same topic about the COVID-19 effect in other countries.
Keywords: COVID-19; Event-study; Indonesia Stock Market; Mean-Adjusted Abnormal Return; Market Model

Introduction

In the stock exchange or stock market, trading activity frequency is one of the elements that becomes the material to see the market reaction towards information that comes in the stock market (Taslim & Wijayanto, 2016).

The increase of frequency in trading transactions caused by high demand will push the stock price to ascend so the return will also be increasing. It is also able to increase the volume of trading transactions. The big trading volume shows that stock is preferred by investors. The investor tendency is to get interested in stocks that give high returns even if it is risky (Taslim & Wijayanto, 2016).

COVID-19 has become a world pandemic, counted globally from 27 September 2020, it has been stated that 32.730.945 COVID-19 cases are confirmed, including 991.224 deaths, reported by WHO (WHO, 2020). In Indonesia, the corona firstly appeared in March. This was stated by the President of Indonesia; Joko Widodo in his speech in the presidential palace, Jakarta, on 2 March 2020. President Jokowi said that two people that went positively affected by Coronavirus were Japanese citizens who came to Indonesia. Up to 27 September 2020 cases that confirmed positive in Indonesia reached 275.213 with the recovered patients are at the number of 203.014 and 10.386 casualties (Official Prevention Unit of COVID-19, 2020). Since the Coronavirus (COVID-19) was found and escalated from the regional crisis in Hubei province, China, that later became a global pandemic, stock market collapse and market volatility went rising high in the world. It even happened in the United States of America's market. The volatility level stock market in the middle of March 2020 has surpassed the biggest volatility condition ever happened in October 1987 and December 2008 which occurred at the end of 1929 and early 1931 (Baker, Bloom, Davis, Kost, Sammon, & Viratyosin, 2020). This COVID-19 pandemic can be classified as 'black swan' since it has economic consequences that are disadvantageous, as Taleb (2005) stated that a black swan is a random event with three characteristics: big impact, uncountable probability, and surprising effect (AlAli, 2020).

The COVID-19 pandemic caused panic for investors. This was evident from the decline of the IHSG which occurred from March 5 to March 9 by 6 percent. The Financial Services Authority (OJK) immediately responded by issuing a policy of movement of the Composite Stock Price Index (IHSG) and allowing the implementation of share repurchases issued by issuers (buyback) without obtaining approval from the General Meeting of Shareholders (RUPS). The issued regulation is contained in OJK Regulation No. 3 / SEOJK.04 / 2020 dated 9 March 2020 concerning Other Conditions as Market Conditions That Fluctuate Significantly in the Implementation of Shares Buyback Issued by Issuers or Public Companies.

Several studies have been found on the impact of COVID-19 on stock market returns, including the impact of the announcement of the first COVID-19 incident and the impact on the stock market (AlAli, 2020; Alam, Alam, & Chavali, 2020; Bash, 2020; Huo & Qiu, 2020), the impact of the pandemic on the Chinese stock market and specifically the characteristics of different companies/sectors in the Chinese stock market (He, Sun, Zhang, & Li, 2020; Huo & Qiu, 2020; Xiong, Wu, Hou, & Zhang, 2020), the specific effect of the number confirmed COVID-19 cases on stock market returns in several countries (Ashraf, 2020; Liu, Manzoor, Wang, Zhang, & Manzoor, 2020; Ruiz Estrada & Lee, 2020; Zeren & Hizarci, 2020). From previous studies, it is found that the result of this study generally presents a stock market reaction which is indicated by the average change of abnormal returns that went descending as the result of the first COVID-19 announcement at the stock markets in several countries.

Based on the result review of the previous studies, the researcher considers that it is necessary to examine the reaction of the Indonesian stock market as a result of the official government announcement when the first case of COVID-19 appeared in Indonesia on March 2, 2020, through abnormal return measurement proxy in the days before and after the announcement of the first COVID-19 case. The research gap that we found was that until the time this research was conducted there had not been any similar research in Indonesia. Moreover, we chose the index variable for each sector as the independent variable whose reaction to the announcement of the first case of COVID-19 was measured as the dependent variable. Research and presentation of this study's result will provide an empirical contribution related to the Indonesian stock market efficiency test through the average change proxy of abnormal return on the non-economic events, both domestically and globally.

Literature Review and Hypothesis Development

In social science, the studies of events or more popularly known as event-studies have been widely carried out in a context that is related to economics and finance. Event studies are often used to measure the efficiency of the stock market in a semi-strong form. An efficient market is called a semi-strong-form efficiency if no single investor gets an abnormal rate of return through any information that is publicly available and is commonly tested by "event-studies". An event study in the stock market sector is a study conducted empirically to analyze the impact of an event on the capital market of a country (Suganda, 2018).

The COVID-19 pandemic event is not an economic event (non-economic event). Research related to event-studies for non-economic event and stock market reaction in Indonesia has been carried out, including political event happened on July 27, 1996 (Suryawijaya & Setiawan, 1998), the inauguration of the President (Asshodiqi, 2016; Pratama, Sinarwati, & Dharmawan, 2015), General Election (Luhur, 2010), Regional Head election (Wardhani, 2012), change of state officers (Islami & Sarwoko, 2012), to natural events/phenomena like a flood (Luhur, 2010; Yuwono, 2013), social, changes in fuel price (Andarini & Rahardjo, 2016; Ningsih & Cahyaningdyah, 2014), terrorism (Sari, 2007; Utama & Hapsari, 2012), to the issuance of government regulation and/or policy (Nanda & Saryadi, 2017; Wibowo, 2017), etcetera.

Another research is also found that observes the economic impact on each pandemic phase (Figure 1) from the beginning of the first case up to the period after the pandemic (Barua, 2020). It also stated that the pandemic period would impact the supply chain performance (Narjoko, 2020) because the social and physical distancing is applied. This is such an interesting one to observe since the industrial sector in the supply chain becomes the dominant economic mover for all this time.

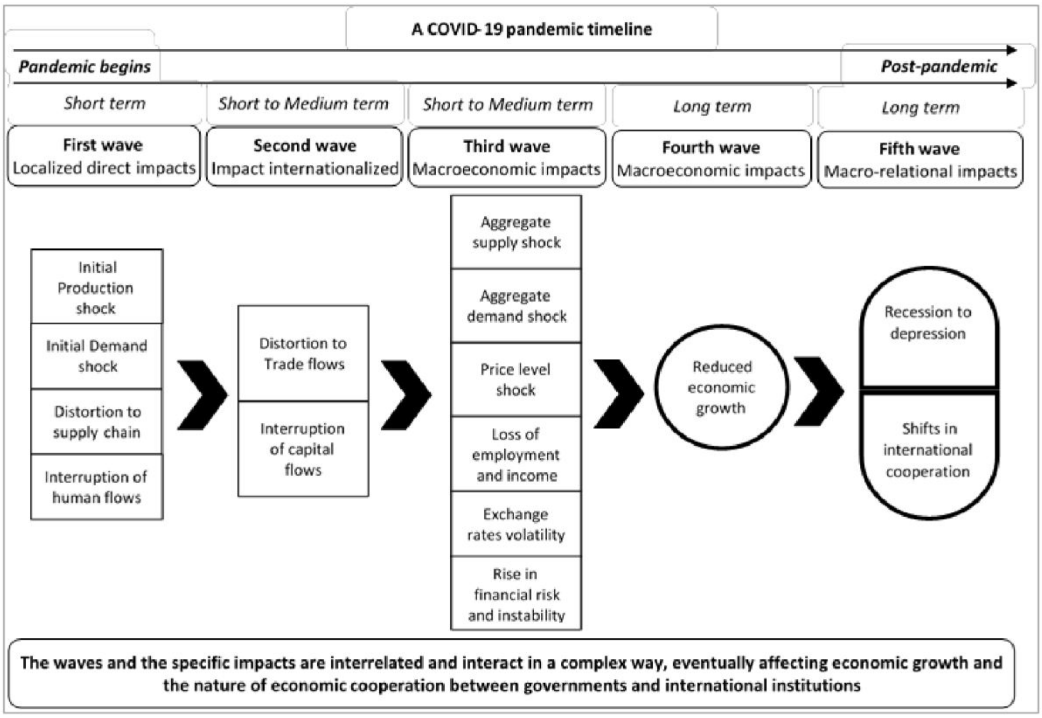

Figure 1 General Mapping of The Possible Economic Impacts of the COVID-19
Source: (Barua, 2020)

This research is expected to enrich the scientific reference for event-studies on non-economic events and their direct impact on the capital market in Indonesia generally and the impact of reactions on the related industrial sector, but still paying attention to the robustness of research results through a critical review of similar research on the impacts COVID-19 among other countries.

Through this research, it is hoped that investors will be able to recognize the behavior of the Indonesian stock market better so that they can make the best investment decision in every event (economic and non-economic) that occurs.

In this study, the hypothesis to test is whether there is a difference in sectoral abnormal return (ABR) and cumulative abnormal return (CABR) on the Indonesian stock exchange before and after the announcement of the first case of positive COVID-19 patients in Indonesia on March 2, 2020.

***H*$_1$**: *the difference in sector-i abnormal return index was found before and after the announcement of the first positive patient case for COVID-19 in Indonesia on March 2, 2020.*

Research Method

The research method used in this research is the event study methodology (ESM). This method is used to take a closer look at the Indonesian stock market's reaction to the COVID-19 pandemic. The event study methodology uses an abnormal return approach so that it can be observed whether the market reaction in obtaining an abnormal return from stock market movement is affected by this pandemic event. The data used in this study are secondary in the form of sectoral indices on the Indonesia Stock Exchange, which are the sectors of Agriculture (SxAGRI), Mining (SxMNG), Basic Industry (SxBSC), Miscellaneous (SxMCL), Infrastructure (SxINF), Financial (SxFNC), Trading (SxTRD) and Manufacture (SxMNF). The research data is sourced from the sectoral index of the Indonesia Stock Exchange from January - March 2020. The observation period was carried out for 10 days before and 10 days after the announcement of the first COVID-19 case in Indonesia, March 2, 2020. Data analysis techniques will use the paired test. sample t-test on abnormal return before and after the event.

This study uses two methods to calculate the abnormal return. Actual return is the return that occurs and is received by the investor in the current period compared to the previous day, either in the form of capital gain or capital loss. Actual return calculation uses the current closing index compared to the previous day's closing index which is calculated by equation (1) as follows:

$$R_{i,t} = \frac{P_{i,t} - P_{i,t-1}}{P_{i,t-1}} \text{..} (1)$$

The expected return is the stock return expected by the investor in the future. The calculation of expected return uses the Single Index Market Model based on the price of securities that fluctuate in the direction of the market price index, which is proxied by the Composite Stock Price Index (IHSG) as shown in equation (2) as follows:

$$Rm_t = \frac{\sum_{t=-10}^{+10} R_{i,t}}{21} \text{..} (2)$$

Abnormal return from sectoral index (i) on the day -t with equation 3 below

$$AR_{i,t} = R_{i,t} - Rm_t \text{.......................................} (3)$$

Ri is the average return of the 10 indexes studied on day t. Rm is the average return index during the estimated range (-10, +10).

Furthermore, the stock market reaction is identified by comparing the results of the abnormal return calculation from equation 3 above (and the likes, for example, the mean-adjusted return as (Brown & Warner, 1985)) against the calculation results of the market model method as one of them was developed (Dodd & Warner, 1983) with the equation (4) below.

$$AMR_{i,t} = R_{i,t} - (\alpha_{i,t} + \beta_{i,t} Rm_t) \text{..............} (4)$$

Where Rmt is the return of the Composite Stock Price Index. $\alpha_{i,t}$ and $\beta_{i,t}$ are the coefficients obtained from the OLS regression during the estimation window (-10, +10). From the results of the calculation and presentation of the graphs of equation (3) and equation (4), the hypothesis to be tested in this study is that there is no difference between cumulative mean-adjusted abnormal return and cumulative market model method before and after the announcement of confirmed cases. COVID-19 on March 2, 2020, in Indonesia.

Result and Discussion

The Indonesia Stock Exchange (BEI) oversees 688 listed issuer companies consisting of 10 industrial sectors; Agriculture, Mining, Basic Industry and Chemical, Miscellaneous Industry, Consumer Goods Industry, Property, Infrastructure, Finance, Trading and Manufacture. Figure 2 shows the 10 sectoral movements in the Indonesia Stock Exchange. The index movement did not fluctuate too much during the study period, which was up on February 17, 2020 to March 16, 2020. The President of Indonesia announced the first positive patient case for COVID-19 in Indonesia on March 2, 2020. The index movement 10 days before the event announcement did not appear to experience too much difference or it can be said that the movement went slope. However, after the announcement, there was a sectoral index market movement in the Indonesian stock market, which was reflected when sectoral movement descended.

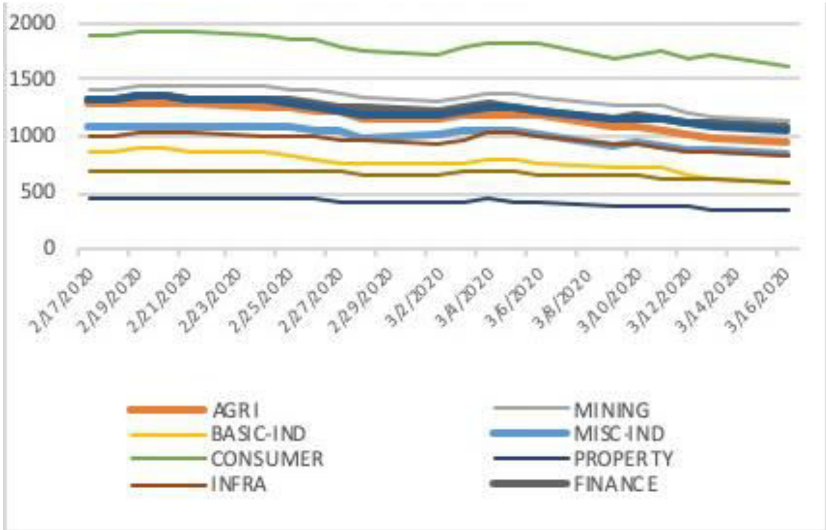

Figure 2 Sectoral Index
Source: Yahoo Finance (accessed at Mei 2020)

The mean-adjusted abnormal return (ABR) and cumulative abnormal return (CABR) for the two models used are illustrated in Figure 3 for the IHSG and sectoral movement in the Indonesian stock market. It can be seen from the figure where the CABR shows a quick descending since day 0 when the first confirmed COVID-19 case in Indonesia was announced that shows a greater effect on the return of the stock market. The average difference between cumulative returns before and after the event date uses the event range (-10, + 10) for the 10 industries sector movement. The results presented in table 1 indicate that there is a statistically significant difference in the mean returns to CAMR at the 99% confidence level.

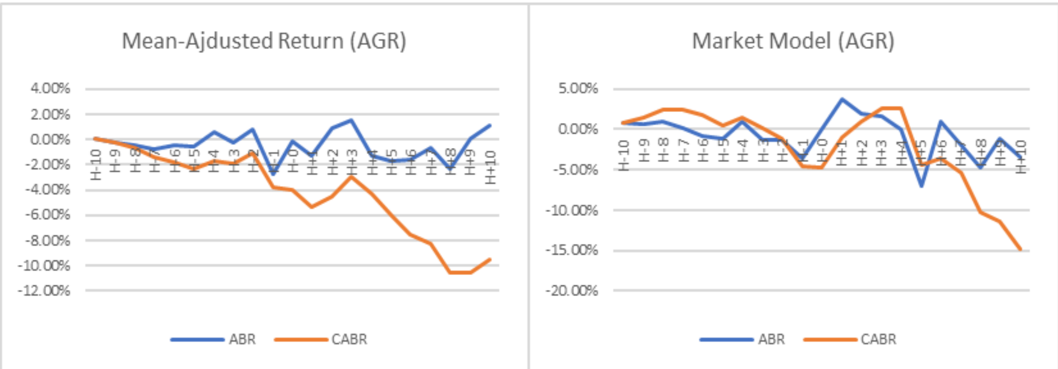

Figure 3 Abnormal Return and Cummulative Abnormal Return

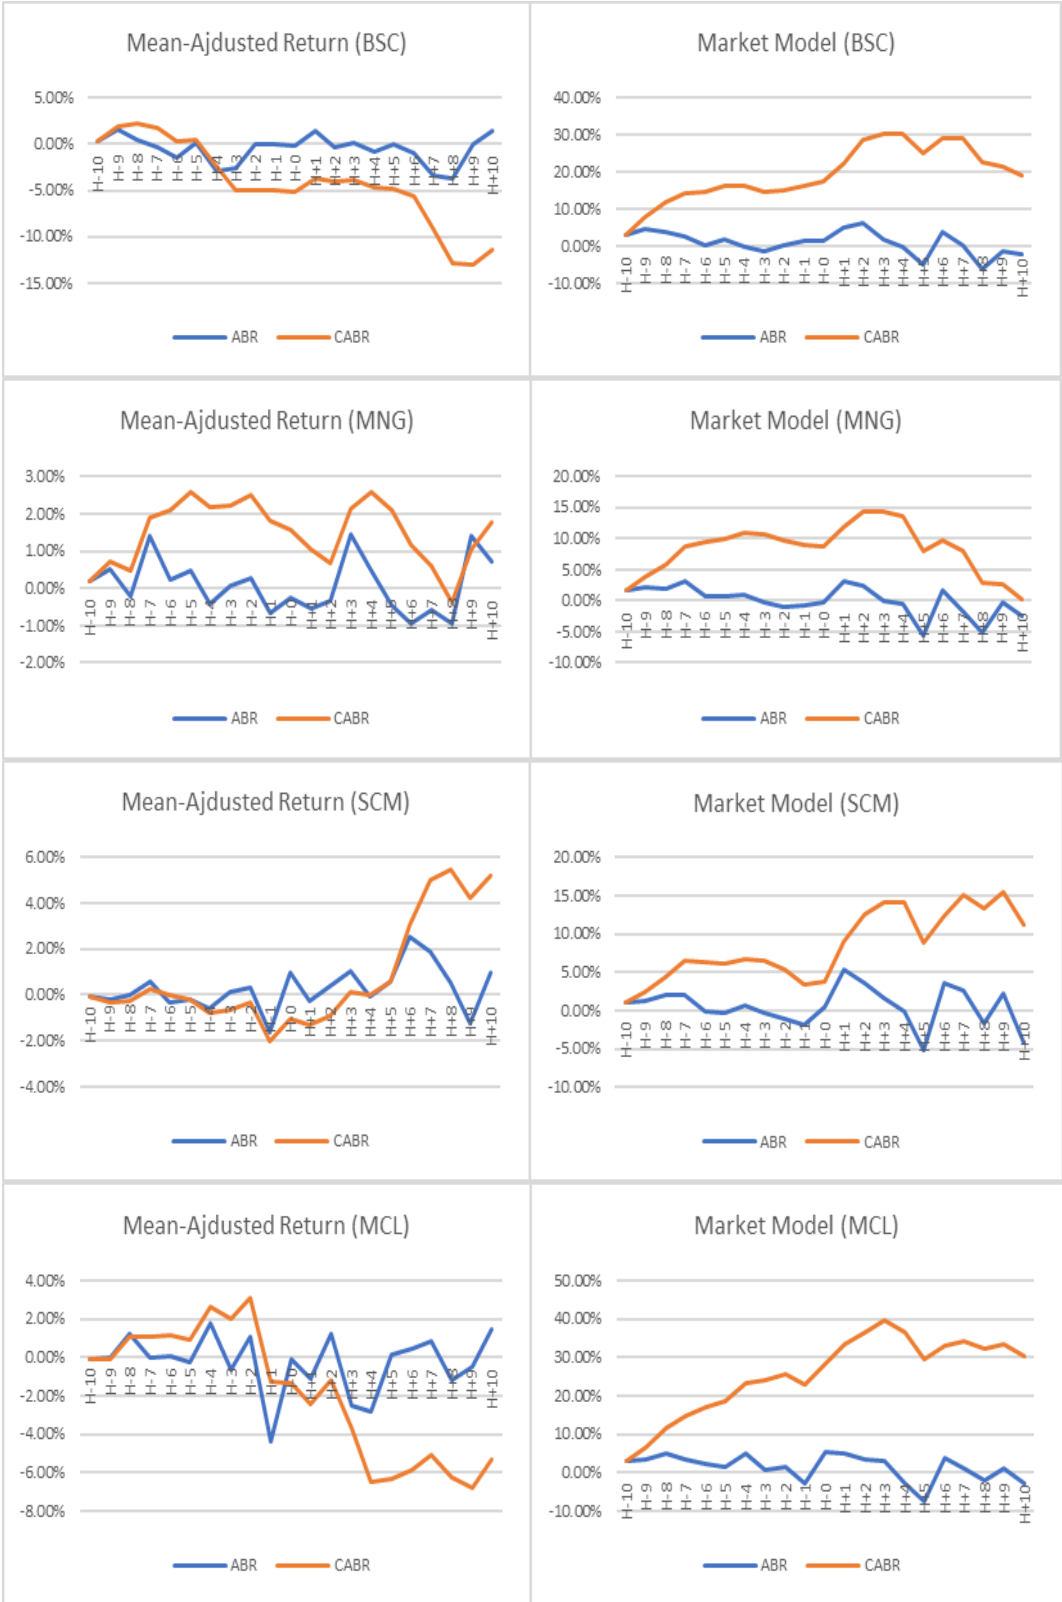

Figure 3 Abnormal Return and Cummulative Abnormal Return (cont')

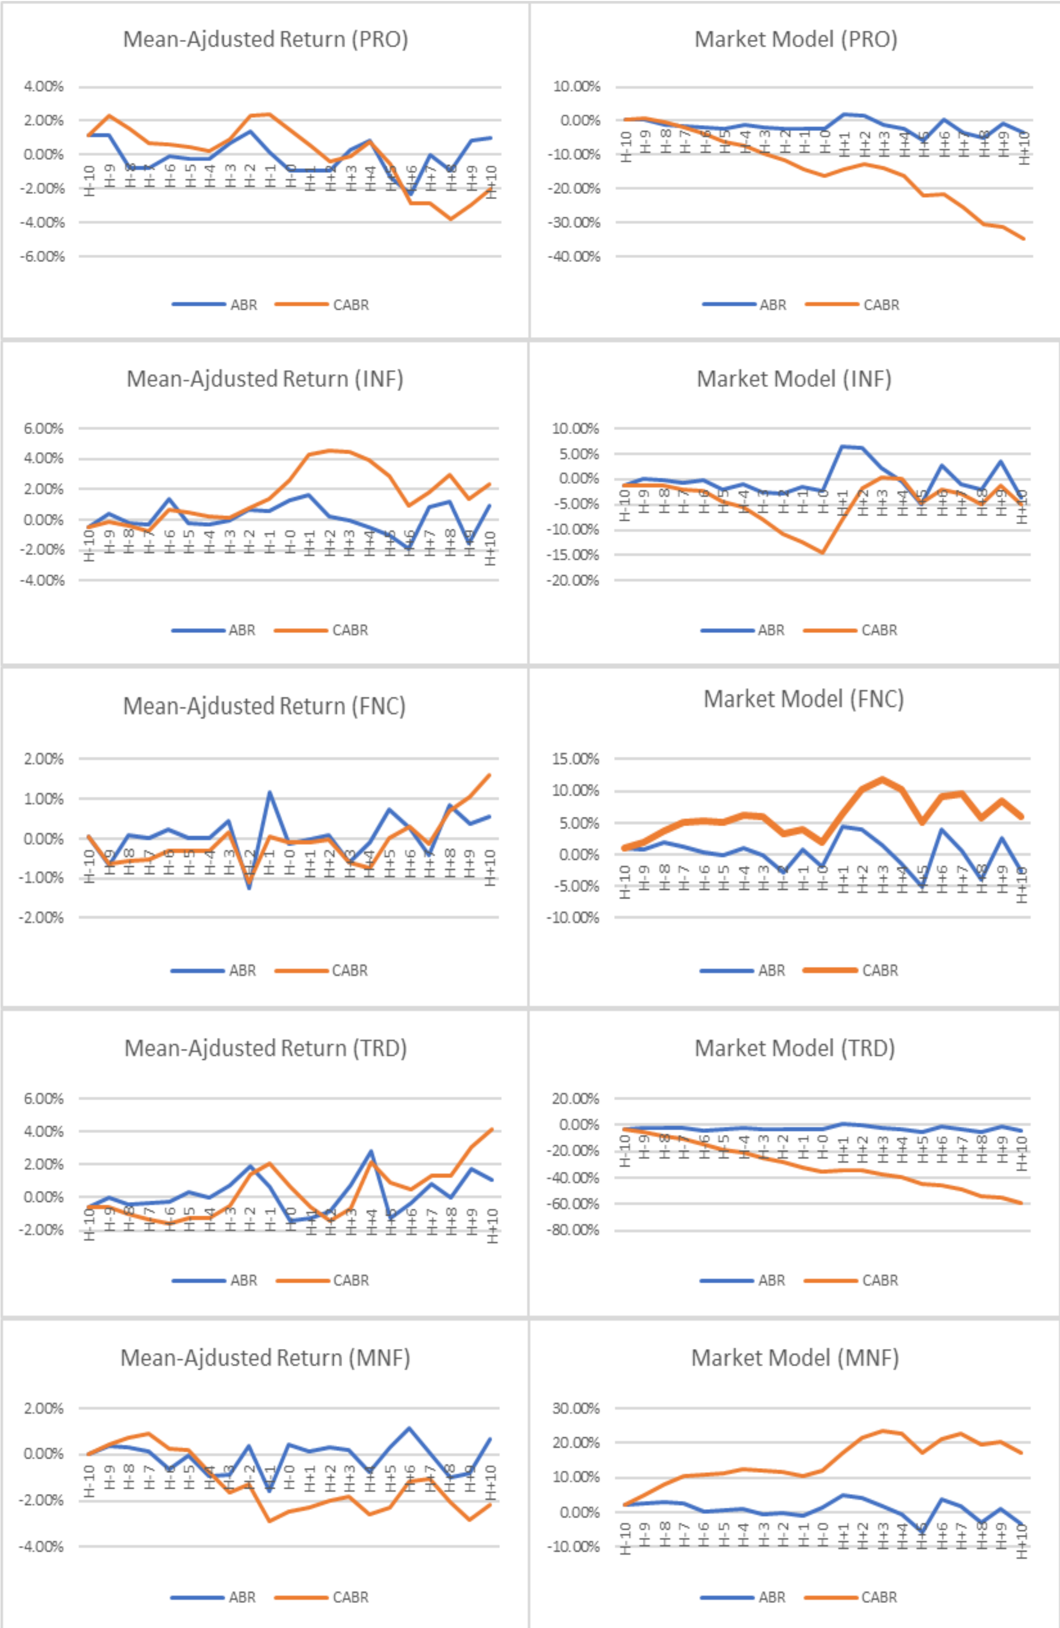

Figure 3 Abnormal Return and Cummulative Abnormal Return (cont')

The analysis result by paired samples test on the mean-adjusted abnormal return method showed a difference between the Abnormal Return (ABR) values before and after the announcement of the first positive patient case in Indonesia announced by the President.

The results of partial analysis on each sector index show that 8 sectors experienced differences in ABR values before and after the announcement of the first positive patient case. They are agricultural sector (SxAGR); basic and chemical industry (SxBSC); various industries (SxMCL); consumer goods industry (SxSCM); property and real estate (SxPRO); transportation and infrastructure (SxINF); finance (SxFNC); trading, services, and investment (SxTRD). Meanwhile, the mining (SxMNG) and manufacturing (SxMNF) sectors have no difference in ABR values before and after the announcement of the first positive patient case in Indonesia. Analysis with the market model shows that only the mining sector (SxMNG) has a difference in abnormal return before and after the the first case of corona sufferer in Indonesia announced.

The finding on 8 sectors that is proven statistically experiencing the abnormal return in Indonesia stock market is in line with the research result (Baldwin & Mauro, 2020) in China stock market and USA (Figure 4 and 5) that shows relative responsiveness of stock on the sectors of transportation industry, property, retail, finance/investment and primary industry/chemicals and consumer goods/personal. On the other side the response difference between the stock market in Indonesia and China/AS can be found in the energy sector/mining where the impact towards Indonesia stock market has not been seen yet statistically, when the significant impact is found in China and USA stock market.

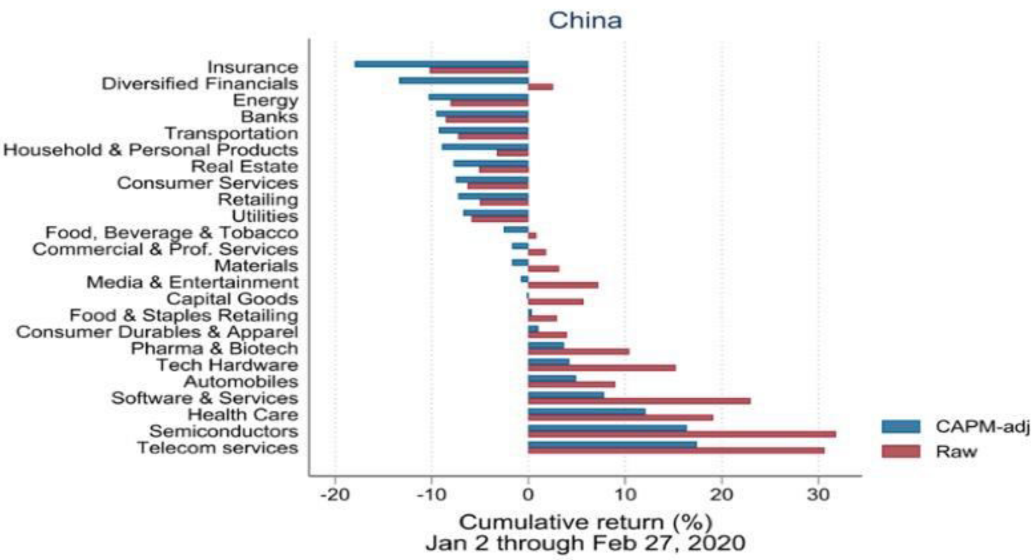

Figure 4 Return of Sector Industry in China during the COVID-19 Pandemic

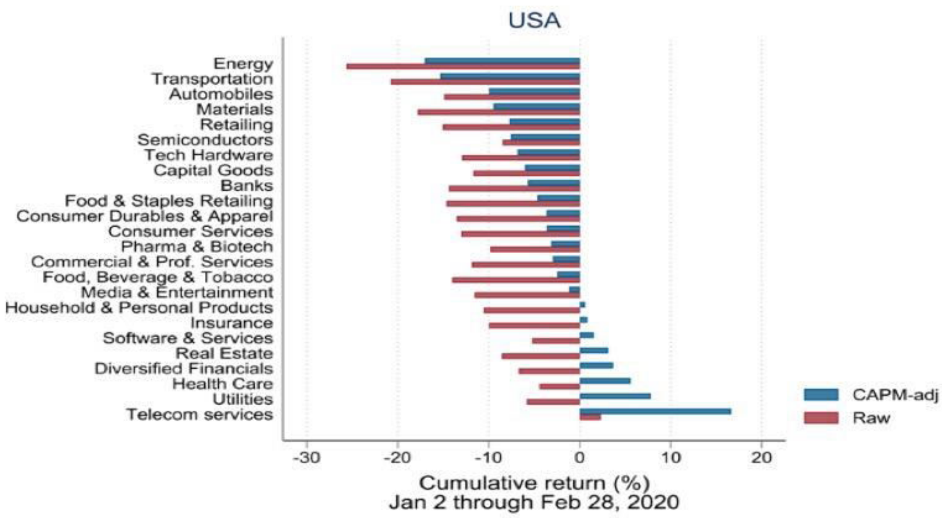

Figure 5 Return of Sector Industry in USA during the COVID-19 Pandemic

This different result shows the expectation gap to the future of company, industry, and market economy reflected from the investor behavior on the stock market (Wagner, 2020). Abnormal return response of the 10 average sectors of stock market industry in Indonesia (0.0057) supports the research (Liu et al., 2020) examining the 21 stock markets response in many countries with abnormal return of Indonesia stock exchange at the number of 0,0069 (absolute).

One of the investors' behaviors during the global pandemic is to avoid the uncertainty (Ashraf, 2020), so the expectation of the future over the industries will influence the investment decision. An investor can use both methods; mean-adjusted abnormal return and market model. From both models, the market model is stronger in depicting the abnormal return achieved because of the market model also counts the risk index and condition of the market index occurred in the stock exchange.

Conclusion

The analysis result shows that the eight industry sectors in Indonesia which are agriculture industry; primary industry and chemicals; consumer goods; property and real estate; transportation and infrastructure; finance; trading, service, and investment give fast response to the government announcement since the first COVID-19 case in Indonesia on 2 March 2020. This reaction explains that those sectors have observed the direct impact of the pandemic on their industries. They are agriculture sector that will be impacted on the bargain side and agriculture product demand, primary industry sector and chemical will face the demand change of medical product, property sector and real estate will deal with the decreasing demand, transportation sector and infrastructure will experience the descending user potency and new development investment, finance industry will change its transaction volume that all happens since the social distancing is applied and government purchasing priority and household changed because of the pandemic. The slower reaction is found in the mining industry, various industry, and manufacture that happen because in short period they haven't been getting the beneficial impact caused by pandemic and still operate to fulfill the market before the pandemic hits. But the analysis result using the market model shows the different abnormal return in mining sector.

This result is in line with the previous research (Ashraf, 2020; Baldwin & Mauro, 2020; Liu et al., 2020; Wagner, 2020) that in the first period of COVID-19 pandemic happened globally, affected industrial sectors related to supply chain, and investor's expectation to the future of certain industry post-pandemic, while in the mid and long term industry will be adapting with the behavioral change of consumer expenditures that will prioritize the primary goods for the daily needs (Pratomo, 2020). This result has beneficial value for investor to understand the stock market behavior in giving response to non-economic events so investor will take the best investment decision on the economic and non-economic events that might happen in the future.

Dr. Jhonni Sinaga, MM., kelahiran Padang Sidempuan, Sumatera Utara, pada 20 Desember 1968. Putra dari ayah dan ibu yang berprofesi sebagai guru ini menamatkan pendidikan dasar hingga menengah atas di Kotamadya Sibolga, Sumatera Utara.

Pada tahun 1990, menyelesaikan pendidikan Bahasa Inggris di Universitas Sumatera Utara. Studi Ekonomi Manajemen juga ditempuh dan diselesaikannya di universitas yang sama pada tahun 1994. Pada tahun 2014, ia menyelesaikan Program Magister Manajemen (S-2; M.M.) di Universitas Mulawarman. Studi Program Doktor Manajemen (S-3) juga ditempuh dan diselesaikannya di universitas yang sama pada tahun 2019. Jhonni Sinaga telah menulis beberapa buku sebagai berikut:

1. Penentu Nilai Perusahaan Dengan Kebijakan Dividen Dan CSR Sebagai Pemoderasi. RV Pustaka Horizon. Oktober 2019.
2. Agency Theory: A Reading. PT. Adler Manurung Press. Agustus 2022 (Sebagai Penulis Kedua).
3. Corporate Finance: A Reading. PT. Adler Manurung Press. Oktober 2022 (Sebagai Penulis Ketiga).
4. Empirical Investment: A Reading. PT. Adler Manurung Press. Oktober 2022 (Sebagai Penulis Kedua).
5. Risk Management: A Reading. PT. Adler Manurung Press. Oktober 2022 (Sebagai Penulis Kedua).
6. Corporate Governance: A Reading. PT. Adler Manurung Press. Oktober 2022.
7. Initial Public Offering: A Reading. PT. Adler Manurung Press. Oktober 2023.

Pada tahun 1996 – Maret 2000, ia bekerja sebagai Kepala Seksi Akuntansi dan Keuangan pada Salim Plantations (Indofood Plantations, Tbk.). Semenjak April 2000, ia dipercaya sebagai *Head of Internal Audit Department* pada B.W. Plantations, Tbk. Pada perusahaan ini karirnya meningkat pada Juli 2003, ia diangkat menjadi *Accounting and Tax Manager*. Per Desember 2005, ia menjabat *Head of Internal Audit Department* pada REA Kaltim Plantations Group (*Subsidiary of REA Holding, a U.K. Public Listed Company at London Stock Exchange*). Sebelas tahun kemudian, mulai Agustus 2016, ia menjadi Head of Operation Finance and Accounting. Pada 01 Agustus 2019, ia resmi mengundurkan diri dari REA Kaltim Plantations Group. Pada April 2020 mendirikan lembaga yang bergerak dalam bidang konsultasi manajemen perusahaan dengan bendera J. J. Manajemen Konsultasi dan pada Nopember 2020 resmi mendirikan entitas yang bergerak dalam bidang transportasi (*trucking and logistic*) dengan bendera PT. JeJe Harapan Transindo (JeJe Trans Group). Kedua bidang usaha ini tumbuh dan berkembang melampaui ekspektasi hingga saat ini.

Penulis adalah pemegang Sertifikat Internasional:
1) Certified International of Program Financial Model (CIPFM).
2) Certified International of Enterprise Risk Management (CIERM).

Semenjak Agustus 2021 menjadi dosen tidak tetap di Universitas Kristen Indonesia (UKI) dan Januari 2022 diangkat sebagai dosen tetap di Universitas Bhayangkara Jakarta Raya hingga saat ini. Selama bekerja sebagai profesional perusahaan, ia aktif sebagai tutor untuk materi-materi seperti *Internal Control*, *Good Corporate Governance* (GCG), *Supervision Management*, *Coaching for Performance*, *Motivation*, *Budgetting*, dan *Finance and Accounting*. Pada tahun 2006, ia berhasil menciptakan konsep usaha perkebunan kelapa sawit baru dengan nama "***PRO EXISTENCE***".

Dr. David Pangaribuan, SE, M.Si
