#### Abstract

This research aims to categorize survey data to determine the level of satisfaction with the services provided by the village government as a public service provider. Villages or sub-districts currently offer services in response to community demand, although only partially or as efficiently as possible. The data collection technique used was distributing questionnaires to the village community. The method used for classification is the machine learning method. Before the classification process, feature selection is carried out at the data pre-processing stage using Particle Swarm Optimization (PSO), which has been proven to increase the accuracy of the classification values. The classification methods employed include Decision Tree (DT), Naive Bayes, Support Vector Machine (SVM), and K-Nearest Neighbor (KNN) algorithms for classification purposes. This study achieves the maximum level of accuracy in decision tree classification, attaining an accuracy rate of 97.74%. Subsequently, the KNN algorithm achieved an accuracy of 77.90%, the Nave Bayes algorithm achieved 64.4%, and the SVM algorithm, which yielded the lowest accuracy value, achieved 59.90%. Following the application of Particle Swarm Optimization (PSO) for optimization, the accuracy of the SVM and KNN algorithms improved to 98.3%. The Decision Tree algorithm achieved a value of 97.77%, while the Naive Bayes technique yielded a value of 69.30%.

**Keywords:** public employees' satisfaction, Classification, Feature Selection, Particle Swarm Optimization, Machine Learning.

#### INTRODUCTION

Public services are provided to members of the broad public who are either citizens or permanent residents of the country in question. Its execution helps achieve civic objectives. Law No. 32 of 2004 deals with regional government. In the framework of regional autonomy, government administration must prioritize community interests, particularly when it comes to the provision of public infrastructure and public administration. The village head is in responsible of managing the local administration, and village representatives work under him or her. Today's society is changing, and as a result, there is a definite need for better, faster, and more precise services as well as more sophisticated services.

The manner that villages or subdistricts are now meeting the requirements of their community may not be optimal; as a result, the community may suffer misery and material harm. To enhance the caliber of the services they receive, raise user satisfaction, and boost the efficacy of their complaint handling, it is essential to swiftly identify the users and provide a mechanism for classifying them[1]. The sole method service providers use to classify issues with the provision of public services is machine learning [2][3].

Several studies on categorizing public service satisfaction have been conducted in the past, including A decision tree approach used in research [4] on the classification of village service satisfaction, which yields an accuracy of 90.66%. Using LDA-SVM to classify complaint reports produces an accuracy of 79.85% [5], and Nave Bayes to classify complaints about public services. The Nave Bayes, KNN, SVM, and boosting algorithms are used to classify public service complaints, and they produce the best SVM accuracy when compared to other approaches[6].

There is a feature selection technique for classification that can increase accuracy by selecting a subset of features from the total dataset[7]. The classification findings are considered when choosing a subset of the feature space for the feature selection process

[8]. When employing the feature optimization method Particle Swarm Optimization (PSO), the accuracy values of the Naive Bayes accuracy optimization method[7], the Support Vector Machine accuracy value optimization method[9], and the KNN algorithm [10] can all be improved. Random Forest, Decision Tree, Nave Bayes, and KNN have all been enhanced with PSO for categorizing diabetic datasets [11]. Particle swarm optimization can increase the accuracy of Support Vector Machine and Decision Tree classification by selecting the right features[12].

The goal of this research is to use one o f the feature selection techniques, the Particle S arm Optimization Algorithm, to add optimization to improve the classification accuracy value of cl assification algorithms such as Decision Tree (DT), Nave Bayes, SVM, and KNN. Classify survey data to ensure satisfaction with the services offered by the village government as a public service provider[4].

#### METHOD

The flow of this research is shown in the figure 1. The dataset for this study came from a survey that was done and given out to residents of the villages in Bekasi's Tambun Selatan subdistrict. Table 1 lists the questionnaire statements. A total of 9999 individuals and fifteen people replied to the survey, which measures respondents' satisfaction with public services through a series of questions, in particular, that service providers provide. Table 2 lists the variables, measurements, descriptions, grades,

and timescales for the research data used The values in Table I correspond to the following categories: represents 1 = Do Not Concur (DNC), 2 = Disagree (DA), 3 = Agree (A), 4 = Strongly Concur (SC).

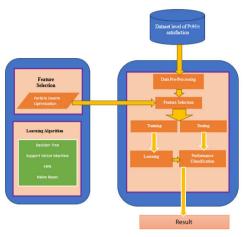

Figure 1. Research Design

The next stage is data pre-processing, where the dataset must be correctly processed before applying the classification model. This allows the dataset to be modeled with a classification algorithm. Microsoft Excel was used to process the survey's result data. The dataset was then split into two clusters and trained Google colaboratory using the k-Mean clustering algorithm. The dataset may be used to create a classification model displayed in Table 2, using the clustering result generated by two clusters to determine the class or target.

| Table 3. Characteristics of I | Research Data |
|-------------------------------|---------------|
|-------------------------------|---------------|

| Cluster   | Sum  | Information  |
|-----------|------|--------------|
| Cluster 1 | 7043 | Satisfied    |
| Cluster 2 | 2956 | Dissatisfied |

Table 1's clustering results show that 7043 people are satisfied with cluster 1 and 2956 people are dissatisfied with cluster 2. Targets, labels, and classes for classification can be developed based on the outcomes of data clustering[13].

Three scenarios are used to divide training and testing data at the beginning of the classification process[14]. In scenario 1, the training data is partitioned into 70% and the testing data into 30%. In another case, the training data is split into 80% and the testing data into 20%. Lastly, the training data is separated into 90%. The proportion of testing data in the scenario is 10%.

In this study, four algorithms—decision trees, Naïve Bayes, support vector machines, and KNN—are used for the algorithm learning stage of classification. There are two stages of classification: the first uses PSO-free classification, and the second uses PSO-based classification.

Eliminating redundant and redundant characteristics from a dataset is the goal of the feature selection step [14], which is essential for processing high-dimensional sample data[15]. Particle Swarm Optimization (PSO) feature selection is used in this work at the learning step to optimize each piece of data generated[16]. PSO is used to select optimal attributes to use in the classification process. PSO requires fitness values when selecting features, to find the best solution candidates. In this process, the fitness value is the accuracy of the classification algorithm, which in the classification process uses the attributes represented by each particle. The representation of the attributes in each part of the dimension in each particle can be made from particles, where the representation is in the form of a binary string 0 and position 1, a value of 0 means that the value of the particle will not be used which is called an inactive value and vice versa for a value of 1 which will be used which is called an active value. Algorithm 1 outlines the steps of the PSO approach.

The DT stage uses[17], which is utilized in e-commerce fraud detection in both the learning stages for the DT classification technique and the DT stage. Algorithm 2 specifically states the steps of the DT method. The second classification uses the Naive Bayes method, which operates under the premise of probabilistically evaluating possibilities[18].

Algorithm 3 specifies the naive Bayes algorithm's phases. The SVM algorithm is the third classification algorithm. Finding a model with the best performance for training data is the main objective of SVM classification[19]. SVM classification can solve linear and non-linear problems using the kernel concept in highdimensional space, and the best hyperplane will be found in this dimensional space to maximize the distance between classes[20].

The K-nearest neighbors (KNN) algorithm is classified as the fourth algorithm for classification. The concept underlying KNN classification is to assign a classification to a new query from an agency by considering the proximity to the majority category. The classification is defined by the category that occurs most frequently[21]. Algorithm 4 specifies the steps of the KNN.

The evaluation of the performance of the classification is the last step. A confusion matrix is used to describe how often the model is produced correctly, and it is based on the accuracy value [22]. Recall and precision are two additional performance indicators used in classification evaluation. Equation (1), equations for precision and recall, and equation (3) are used to calculate the accuracy value. A classification model can additionally include Receiver Operating Characteristics (ROC) [22][23] and Area Under the Curve (AUC) [24] in addition to the confusion matrix, depending on how well the predictions performed.

Algorithm 1 Particle Swarm Optimization[25]

- 1: Assume that there are N particles in the group or swarm.
- 2: To obtain X1, create a random initial population X with a range of X (B) and X (A). Then, particle j and its velocity in iteration I are designated as X(i) j and V(i) j, respectively, making the initial particles X1(0), X2(0),... XN (0) Assume that there are N particles in the group or swarm.
- 3: Find out each particle's speed. Set iteration i to be 1.
- 4: Find two crucial parameters for each particle in the ith iteration.
- 5: Calculate the velocity of particle j in iteration 1 of vi, where m=w. vi,m+c 1R(pbesti,m) +c 2R(gbestm).
- 6: Calculate the particle j's speed in iteration I of the formula vi,m=w. vi,m+c 1R(pbesti,mxi,m) +c 2R(gbestmxi,m).

Algorithm 2 Decision Tree [25]

- 1: Create attributes
- 2: First, calculate the entropy value, and then choose the properties

$$entropi = \sum_{i=1}^{l} -pi * log_2 pi$$

3: Gaining information by mending

- 4: Determine the knowledge obtained from the output.
- 5: Repetition of Step 2

Algorithm 3 Naïve Bayes [26]

- 1: To practice and compare your vocabulary, create a document.
- 2: The equation formula can be used to find probability values.

$$p(A|B) = \frac{P(B|A*P(A))}{P(B)}$$

3: Documents are classified so that the largest value of the class is visible.

Algorithm 4 KNN[27]

- 1: Determine the K value.
- 2: Utilize the Euclidean distance formula to determine the separation between the data.

$$Ed = \sqrt{(a1 - b1)^2 + ... (an - bn)^2}$$

3: The distance computation results are used to determine the K nearest neighbors.

#### **RESULT AND DISCUSSION**

Using the Python programming language and its built-in machine learning library, classification models using decision trees, Naive Bayes, SVM, and KNN are created [28].

#### Making a Decision Tree Model

Python was used to implement the DT classification model without PSO optimization, and the results were an accuracy score of 0.9774, a precision score of 1, and a recall score of 0.943. The confusion matrix DT without PSO is shown in Table 4, and the AUC and Roc values are shown in Figure 2.

Classification optimization using PSO in Python programming with a composition of 70% training and 30% testing data. The results of several trials carried out the best results for classification optimization with PSO using particles of 50, dimensions of 14, and a fitness value of 0.5 at 1300 iterations. This resulted in a reduction in features/variables from 15 to 4 features. Next, the PSO results are made into a classification model using decision trees, naïve Baves, SVM, and KNN.The accuracy, precision, and recall values for DT classification with additional PSO optimization were 0.9777, 1, and 0,944, respectively. AUC and Roc values are shown in Figure 3, and Table 5 shows a confusion matrix with PSO.

An AUC of 0.972 (excellent classification) is generated by the data in Figure 3 of the ROC graph.

#### Making a Naïve Bayes Classification Model

In this study, naive Bayes classification is performed using Python programming with 70% training data and 30% test data. Without PSO optimization, the Naive Bayes classification model yielded accuracy, precision, and recall values of 0.644, 0.548, and 0.623, respectively. The confusion matrix DT without PSO is shown in Table 6, and the AUC and Roc values are shown in Figure 4.

After feature selection, there were 9 features left out of the initial 15 features before PSO optimization. Accuracy was 0.693, precision was 0.960, and recall was 0.245 for naive Bayes classification with additional PSO optimization. AUC and Roc values are shown in Figure 5 and are part of the confusion matrix in Table 7 with PSO.

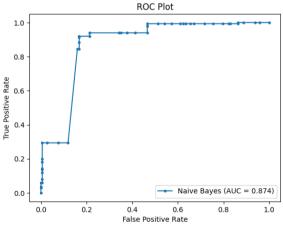

Figure 5. AUC Dan ROC Naïve Bayes With PSO

The ROC graph results in Figure 5 with an AUC of 0.874 (excellent classification). **Making an SVM classification mode** 

The Python programming language is used to implement the SVM classification in this study, which uses 70% training data and 30% testing data. The accuracy value was 0.599, the precision was 0, and the recall was 0, after using the SVM classification model without PSO optimization. Figure 6 shows the AUC and Roc values, while Table 8 contains the DT confusion matrix without PSO.

С

Δ

After feature selection, there were only 8 features left out of the initial 15 features before PSO optimization. A score of 0.983 was obtained for accuracy, 0.960 for precision, and 0.959 for recall for SVM classification with PSO optimization. Figure 7 displays the AUC and Roc values, while Table 9 is a confusion matrix with PSO.

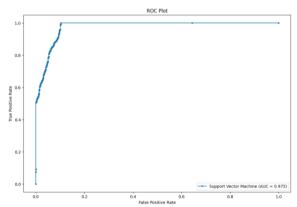

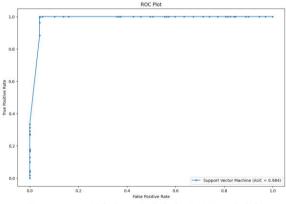

Figure 6. AUC Dan ROC SVM Without PSO

An AUC of 0.975 (excellent classification) is generated by the data in Figure 6 of the ROC graph. The results of the ROC graph in Figure 7 result in an AUC of 0.984 (excellent classification).

#### **Modeling KNN Classification**

Using Python programming, the KNN classification in this study uses 70% training data and 30% testing data. Without PSO optimization, the KNN classification model produced accuracy values of 0.779, precision values of 1, and recall values of 0.522. The confusion matrix DT without PSO is shown in Table 10, and the AUC and Roc values are shown in Figure 8.

Prior to PSO optimization, there were 15 initial features; after feature selection, there were only 6. The accuracy, precision, and recall metrics for KNN classification with additional PSO optimization were 0.983, 0.960, and 0.959, respectively. Figure 9 shows the AUC and Roc values from Table 11's confusion matrix with PSO.

According to figure 8, the ROC curve from the outcomes of the KNN computation without PSO optimization yields an AUC of 0.795 (good classification).

# Models of Classification Algorithm Comparison

The graph in Figure 10 can be viewed as a comparison before feature optimization using PSO based on the output of the classification models built by DT, Naive Bayes, SVM, and KNN.

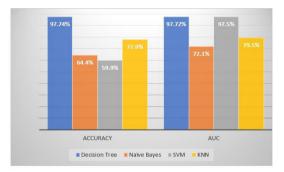

Figure 10. Comparison Chart for Classification Models

In comparison to the classification models created by Naive Bayes, SVM, and KNN, the Decision Tree algorithm in Figure 10's graph had the highest accuracy, with an accuracy value of 0.9774 and an AUC value of 0.972. The classification model is then optimized using PSO for each algorithm. Following optimization with PSO, Figure 11 shows a comparison graph of 4 (algorithms).

The SVM method in the classification model had an increase in accuracy following PSO of up to 38.4%, whereas DT saw the smallest increase in accuracy at 0.03%. The classification model for public service satisfaction with services offered by the village administration in Tambun Selatan sub-district is compared in the following, as shown in Table 11.

Figure 11. Comparative Models of Classification + PSO Chart

Table 11 demonstrates the customer service satisfaction categorization model's results, which reveal that the Decision Tree method had the best accuracy (97.74%) and the SVM approach had the lowest (59.90%). The algorithm's performance SVM in the classification model after optimization with PSO increased significantly, rising by 38.4% from the results of the prior classification model to 59.90% after optimization with PSO to 98.3%. Based on Table 9, the DT method was selected as the best algorithm for classifying public service happiness without PSO optimization, while the SVM algorithm was selected as the best algorithm for classifying public service satisfaction with PSO optimization.

Table 11. Models for Classifying Public Service Satisfaction Comparatively

| Satisfaction Comparatively |           |        |        |          |
|----------------------------|-----------|--------|--------|----------|
|                            | Algorithm | No PSO | +PSO   | Increase |
|                            | Decision  | 97.74% | 97.77% | 0.03%    |

#### CONCLUSION

Before optimization, each algorithm in the classification model was evaluated. The decision tree algorithm achieved the highest accuracy of 97.74% and an AUC of 97.2% on the ROC graph. The KKN algorithm followed with an accuracy of 77.90% and an AUC of 79.5%. The Naïve Bayes algorithm had an accuracy of 64.4% and an AUC of 72.1%. The

SVM algorithm had the lowest accuracy of 59.90% and an AUC of 97.5%. By implementing Particle Swarm Optimization (PSO) for optimization, the SVM algorithm, which initially had the lowest accuracy value, experienced a significant increase of 38.4% in accuracy. As a result, the SVM algorithm achieved an accuracy value of 98.3%, and the ROC graph showed an Area Under the Curve (AUC) of 98.4%.

Similarly, the K-Nearest Neighbors (KNN) algorithm achieved an accuracy value of 98.3% with an AUC value of 98% after starting with an accuracy value of 20.40%. The DT algorithm achieved a 97.77% accuracy rate, with an AUC value of 97.2%. The lowest accuracy rate after optimization was observed with Naïve Bayes, which achieved a 69.30% accuracy rate with an AUC value of 87.4%. The utilization of Particle Swarm Optimization (PSO) for feature selection has effectively enhanced the accuracy of every model, hence enhancing the classification process for each model.

SVM, KNN, Naïve Bayes, and Decision Tree are optimized using PSO to identify the features or variables that have the greatest impact on public service satisfaction. The constructed model has been demonstrated to enhance the accuracy of each algorithm, enabling the classification model to assess the level of satisfaction with public services.

In order to get a greater level of precision, it is advisable to incorporate additional variables or characteristics into the data for future investigation. For advanced algorithms, it is optimal to integrate feature extraction, feature selection algorithms, and other classification approaches, along with feature selection algorithms.

#### Abstract

The purpose of this study is to categorise the survey data in order to ascertain the degree of satisfaction with the services offered by the village administration as a provider of public services. Villages or subdistricts currently provide services in response to community requests, although not entirely or as efficiently as they could. Dissatisfaction and harm to the community, both tangible and intangible, may result from this. The required techniques for classifying service users have been made available in order to enhance service and efficiency in managing complaints from service users, finding patterns, and delivering prompt solutions to improve service products. In order to gather data for this study, guestionnaires were given out to residents of villages and subdistricts who use public services. Excel has been used to examine the data, which preprocesses the data to produce a categorization model. Data is organized to obtain labels or targets during the pre-processing step so that algorithmic classification can be used to process it. The Decision Tree (DT), Naive Bayes, Support Vector Machine (SVM), and K-Nearest Neighbor (KNN) algorithms are used for classification. This research produced the highest accuracy value in decision tree classification, which received the highest accuracy value of 97.74%. It was followed by the KNN algorithm, which obtained an accuracy of 77.90%, the Nave Bayes algorithm, 64.4%, and the algorithm that produced the smallest accuracy value, the SVM algorithm, at 59.90%. Following optimization, the SVM and KNN algorithms had accuracy values of the 98.3%, the Decision Tree Algorithm had a value of 97.7%, and the Naïve Bayew approach had a value of 69.3%.

#### INTRODUCTION

Public services are provided to members of the broad public who are either citizens or permanent residents of the country in question. Its execution helps achieve civic objectives. Law No. 32 of 2004 deals with regional government. In the framework of regional autonomy, government administration must prioritize community interests, particularly when it comes to the provision of public infrastructure and public administration. The village head is in responsible of managing the local administration, and village representatives work under him or her. Today's society is changing, and as a result, there is a definite need for better, faster, and more precise services as well as more sophisticated services.

The manner that villages or subdistricts are now meeting the requirements of their community may not be optimal; as a result, the community may suffer misery and material harm. In order to enhance the caliber of the services they receive, raise user satisfaction, and boost the efficacy of their complaint handling, it is essential to swiftly identify the users and provide a mechanism for classifying them [1]. The sole method used by service providers to classify issues with the provision of public services is machine learning [2] [3].

Several studies on the categorization of public service satisfaction have been conducted in the past, including: A decision tree approach used in research [4] on the classification of village service satisfaction yields an accuracy of 90.66%. Using LDA-SVM to classify complaint reports, which produces an accuracy of 79.85% [5], and Nave Bayes to classify complaints about public services The Nave Bayes, KNN, SVM, and boosting algorithms are used to classify public service complaints, and they produce the best SVM accuracy when compared to other approaches [6].

There is a feature selection technique for classification that can increase accuracy by selecting a subset of features from the total dataset [7]. The findings of the classification are taken into consideration when choosing a subset

#### ISSN 2089-8673 (Print) I ISSN 2548-4265 (Online) Volume XX, Issue XX, Month 20XX

of the feature space for the feature selection process [8]. When employing the feature optimization method PSO, the accuracy values of the Naive Bayes accuracy optimization method [7], the Support Vector Machine accuracy value optimization method [10], and the KNN algorithm [9] can all be improved. Random Forest, Decision Tree, Nave Bayes, and KNN have all been enhanced with PSO for the categorization of diabetic datasets [11]

The goal of this research is to use one o f the feature selection techniques, the Particle S warm Optimization Algorithm, to add optimizatio n to improve the classification accuracy value of classification algorithms such as Decision Tree (DT), Nave Bayes, SVM, and KNN.The researc h is current with the classification of service sati sfaction level survey results, which employed su rveys in many Tambun subdistrict villages in ad dition to one sub-district [4].

#### METHOD

Alur penelitian ini ditunjukan pada gambar 1.

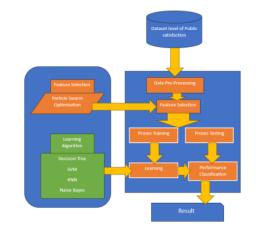

Figure 1. Identification of Sentiment Polarity using SVM and Levenshtein Distance

The dataset for this study came from a survey that was done and given out to residents of the villages in Bekasi's Tambun Selatan subdistrict. A total of 9999 individuals and fifteen people replied to the survey measures respondents' satisfaction with public services through a series questions, in particular, that service providers provide. Table 1 lists the variables, measurements, descriptions, grades, and timescales for the research data used.

The next stage is data pre-processing, where the dataset must be correctly processed before the classification model is applied. This allows the dataset to be modeled with a classification algorithm. Microsoft Excel was used to process the survey's result data. The dataset was then split into two clusters and trained Google Colab using the k-Mean clustering algorithm. The dataset may be used to create a classification model, which is displayed in Table 2, using the clustering result generate of by two clusters to determine the class or target.

|-----------|------|-----------|
| Cluster 2 | 2956 | Non       |
|           |      | Satisfied |

Table 2's clustering results show that, overall, 7043 people are satisfied with cluster 1 and 2956 people are dissatisfied with cluster 2. Targets, labels, and classes for classification can be developed based on the outcomes of data clustering [12].

Three scenarios are used to divide training and testing data at the beginning of the classification process [13]. The training data in scenario 1 is divided into 70%, the testing data is 30%, the training data is 80%, the testing data is 20%, and the training data is 90%. The testing data is 10% in scenario 2.

In this study, four algorithms—decision trees, naïve bayes, support vector machines, and KNN—are used for the algorithm learning stage of classification. There are two stages of classification: the first uses PSO-free classification, and the second uses PSO-based classification.

Eliminating redundant and superfluous characteristics from the data set is the aim of the feature selection step [13], which is essential for processing high-dimensional sample data [14]. PSO feature selection is used in this work at the learning step to optimize each piece of data generated [15]. Algorithm 1 outlines the PSO approach's steps.

The DT stage uses [17], which is utilized in e-commerce fraud detection in both the learning stages for the DT classification technique and the DT stage. Algorithm 2 specifically states the DT method's steps. The second classification uses the Naive Bayes method, which operates under the premise of probabilistically evaluating possibilities [17].

Algorithm 3 specifies the naive Bayes algorithm's phases. The SVM algorithm is the third classification algorithm. Finding a model with the best performance for training data is the main objective of SVM classification [18]. SVM classification can solve linear and non-linear problems using the kernel concept in highdimensional space, and the best hyperplane will be found in this dimensional space to maximize the distance between classes [19].

The KNN algorithm is the fourth classification algorithm. The idea behind KNN classification is to determine a classification

based on the outcomes of a new agency query based on the closeness of the majority category, with the classification result being determined by the category that appears the most frequently [20]. Algorithm 4 specifies the steps of the KNN.

The evaluation of the performance of the classification is the last step. A confusion matrix is used to describe how often the model is produced correctly, and it is based on the accuracy value [21]. Recall and precision are two additional performance indicators used in classification evaluation. Equation (1), equations for precision and recall, and equation (3) are used to calculate the accuracy value. A classification model can additionally include Receiver Operating Characteristics (ROC) [21] [22] and Area Under the Curve (AUC) [23] in addition to the confusion matrix, depending on how well the predictions performed.

#### RESULT AND DISCUSSION

programming Using the Python language and its built-in machine learning library, classification models using decision trees, Naive Bayes, SVM, and KNN are created [27].

#### Making a Decision Tree Model

Python was used to implement the DT classification model without PSO optimization, and the results were an accuracy score of 0.9774, a precision score of 1, and a recall score of 0.943. The confusion matrix DT without PSO is shown in Table 3, and the AUC and Roc values are shown in Figure 2.

The accuracy, precision, and recall values for DT classification with additional PSO optimization were 0.9777, 1, and 0,944, respectively. AUC and Roc values are shown in Figure 3, and Table 4 shows a confusion matrix with PSO.

#### Making a Naïve Bayes Classification Model

In this study, naive Bayes classification is performed using Python programming with 70% training data and 30% test data. Without PSO optimization, the Naive Bayes classification model yielded accuracy, precision, and recall values of 0.644, 0.548, and 0.623, respectively. The confusion matrix DT without PSO is shown in Table 5, and the AUC and Roc values are shown in Figure 4.

After feature selection, there were 9 features left out of the initial 15 features before PSO optimization. Accuracy was 0.693, precision was 0.960, and recall was 0.245 for naive Bayes classification with additional PSO optimization. AUC and Roc values are shown in Figure 5 and are part of the confusion matrix in Table 6 with PSO.

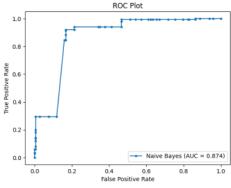

Figure 5. AUC Dan ROC Naïve Bayes With PSO

The ROC graph results in Figure 5 with an AUC of 0.874 (excellent classification). **Making an SVM classification mode** 

The Python programming language is used to implement the SVM classification in this study, which uses 70% training data and 30% testing data. The accuracy value was 0.599, the

#### ISSN 2089-8673 (Print) I ISSN 2548-4265 (Online) Volume XX, Issue XX, Month 20XX

precision was 0, and the recall was 0, after using the SVM classification model without PSO optimization. Figure 6 shows the AUC and Roc values, while Table 7 contains the DT confusion matrix without PSO.

After feature selection, there were only 8 features left out of the initial 15 features before PSO optimization. A score of 0.983 was obtained for accuracy, 0.960 for precision, and 0.959 for recall for SVM classification with PSO optimization. Figure 7 displays the AUC and Roc values, while Table 8 is a confusion matrix with PSO.

#### Modeling KNN Classification

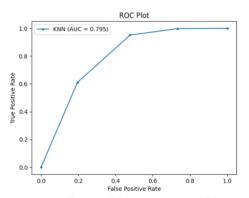

Using Python programming, the KNN classification in this study uses 70% training data and 30% testing data. Without PSO optimization, the KNN classification model produced accuracy values of 0.779, precision values of 1, and recall values of 0.522. The confusion matrix DT without PSO is shown in Table 9, and the AUC and Roc values are shown in Figure 8.

Prior to PSO optimization, there were 15 initial features; after feature selection, there were only 6. The accuracy, precision, and recall metrics for KNN classification with additional PSO optimization were 0.983, 0.960, and 0.959, respectively. Figure 9 shows the AUC and Roc values from Table 10's confusion matrix with PSO.

Figure 8. AUC Dan ROC KNN Without PSO

According to figure 8, the ROC curve from the outcomes of the KNN computation without PSO optimization yields an AUC of 0.795 (good classification).

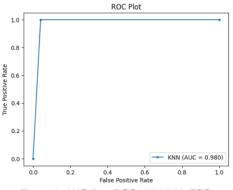

Figure 9. AUC Dan ROC KNN With PSO

The AUC of 0.980 (excellent classification) is produced by the ROC curve using the results of the KNN calculation with PSO optimization based on figure 9.

# Models of Classification Algorithm Comparison

The graph in Figure 10 can be viewed as a comparison before feature optimization using PSO based on the output of the classification models built by DT, Naive Bayes, SVM, and

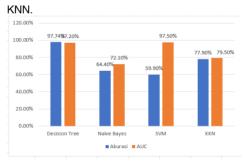

Figure 10. Comparison Chart for Classification Models

In comparison to the classification models created by Naive Bayes, SVM, and KNN, the Decision Tree algorithm in Figure 10's graph had the highest accuracy, with an accuracy value of 0.9774 and an AUC value of 0.972. The classification model is then optimized using PSO for each algorithm. Following optimization with PSO, Figure 11 shows a comparison graph of 4 (algorithms).

Figure 11. Comparative Models of Classification + PSO Chart

The SVM method in the classification model had an increase in accuracy following PSO of up to 38.4%, whereas DT saw the smallest increase in accuracy at 0.03%. The classification model for public service satisfaction with services offered by the village administration in Tambun Selatan sub-district is compared in the following, as shown in Table 11.

Table 11. Models for Classifying Public Service Satisfaction Comparatively

| Algoritma                    | Tanpa<br>PSO | +PSO   | Kenaikan |
|------------------------------|--------------|--------|----------|
| Decision<br>Tree             | 97.74%       | 97.77% | 0.03%    |
| Naïve<br>Bayes               | 64.40%       | 69.30% | 4.90%    |
| Support<br>Vector<br>Machine | 59.90%       | 98.3%  | 38.40%   |

#### ISSN 2089-8673 (Print) I ISSN 2548-4265 (Online) Volume XX, Issue XX, Month 20XX

#### K-Nearest 77.90% 98.30% 20.40% Neighbor

Table 11 demonstrates the customer service satisfaction categorization model's results, which reveal that the Decision Tree method had the best accuracy (97.74%) and the SVM approach had the lowest (59.90%). The SVM algorithm's performance in the classification model after optimization with PSO increased significantly, rising by 38.4% from the results of the prior classification model to 59.90% after optimization with PSO to 98.3%. Based on Table 9, the DT method was selected as the best algorithm for classifying public service happiness without PSO optimization, while the SVM algorithm was selected as the best algorithm for classifying public service satisfaction with PSO optimization. CONCLUSION

The decision tree algorithm, which received the highest accuracy value of 97.74%, was followed by the KNN algorithm, which received an accuracy of 77.90%, the Nave Bayes algorithm, which received an accuracy of 64.4%, and the SVM algorithm, which received the smallest accuracy value of 59.90%. The accuracy value of the SVM method, which had the lowest accuracy value before optimization, increased after adding optimization using PSO by 38.4%, giving the algorithm an accuracy value of 98.3%. It was followed by the KNN algorithm, which saw an accuracy value rise of 20.40%, bringing the accuracy number to 98.3 percent. The DT algorithm had a 97.77% accuracy rate and Nave Bayes, with an accuracy rating of 69.30%, had the lowest accuracy after optimization. It is possible to determine whether the public services given by the village government are good or need to be enhanced further in order to continue serving the community by raising the accuracy value created by the accuracy values of the four algorithms..

In order to obtain higher accuracy values, it is suggested that future studies combine feature extraction, feature selection algorithms, and other classification methods and feature selection algorithms.

#### ACKNOWLEDGMENT

We are grateful that this research was funded by LPPMP, the manager of research and community service at Bhayangkara Jakakrta Raya University, and that the village administration helped with data collection for this research.

# [JANAPATI] Editor Decision

2023-11-20 07:55 AM

Wowon Priatna:

We have reached a decision regarding your submission to Jurnal Nasional Pendidikan Teknik Informatika : JANAPATI, "PARTICLE SWARM OPTIMIZATION FOR OPTIMIZING PUBLIC SERVICE SATISFACTION LEVEL CLASSIFICATION".

Our decision is to: Revision Required

Please revise your manuscript based on reviewer's comment. The revision will be deliver to the 2nd round review. The revision should be submitted no longer than November 27, 2023.

Reviewer B: Recommendation: Revisions Required
